Public Health Implications of Tropical and Imported Diseases*

Strategy against the Global Spread of Disease

THOMAS PARRAN, M.D., F.A.P.H.A.

Surgeon General, U. S. Public Health Service, Washington, D. C.

THIS is a public health war. In every theater, the fighting forces of the United Nations and the enemy alike are exposed to diseases of public health importance. In most of our combat areas, epidemic diseases are rife in the native population. Malaria encircles the globe, and is the foremost problem of military medicine in the majority of war theaters. Cholera prevails in India, China, and the Southwest Pacific; dysentery throughout the Tropics. In North Africa, the Near East, and Eastern Europe are the world's great reservoirs of louse-borne typhus. After an absence of many years, Germany acknowledges its presence there. Yellow fever is epidemic in Africa; it exists in jungle form in South America; and the mosquito vector thrives in the United States, the Mediterranean area, India, Burma, the Southwest Pacific. Dengue, borne by the same mosquito, occurs in the same regions. Every-

where in overseas fighting, we are confronted with venereal infections frequently pandemic, and with a high tuberculosis rate.

It is inevitable, therefore, that our fighting men are exposed to extraordinary disease hazards and that many will succumb. In every war of recorded time, disease has caused more military casualties than have battle wounds. This war is no exception.

Battle casualties cease when the fighting stops. Disease casualties continue to take their toll. In the three years after World War I, more people died of starvation and disease than were killed in the four years of fighting. Disease problems no less than the strictly military problems are unprecedented and infinitely complex in this global war. Consider, for example, the mass displacement of population—an estimated 12–15 millions of people in Europe—political and military prisoners, slave labor, and refugees. After the war, nothing will thwart the urge to go home. The more hunger, lowered resistance,

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

and epidemics, the more uncontrollable the dispersion toward home. Foci of infection will thereby be scattered into the remotest villages throughout Europe. In this total war, health problems also are total in their nature, affecting total populations.

Our strategy against the spread of disease, therefore, must be global in its scope. It is being developed in three overlapping phases. The *first* is directed toward the protection of our troops and of vulnerable areas while the fighting is on. The *second* deals with the emergency restoration of health conditions in reoccupied zones, through relief of starvation and epidemic control—a prelude to rehabilitation. The *third* evolves into world-wide collaboration for improved health.

From the military point of view, our public health defenses at home, at outlying bases, and in combat zones must parallel military efficiency in the total job of defeating the enemy. The enemy faces the same disease threats to his striking power; therefore, superiority in health protection of our troops is as much a requirement for victory as superiority in forces and supplies. No other military force in the world approaches ours in the proportion or competence of its medical and health components. For this superiority we suffer gladly the privations necessary at home. Yet there is a limit beyond which excellence in military health service defeats its total purpose through deprivation on the production front. Medical and health services in many communities now are below the margin of safety, as you know.

The health of military personnel requires the strengthening of health measures in surrounding civilian areas. This is true abroad no less than at home. Since we are fighting in the tropics and subtropics on a vast scale, we must prevent insect vectors from being transferred to vulnerable areas

abroad, where they may hamper military operations, or to home areas where they can gain a foothold and disrupt war production.

Pestilence always has accompanied and followed in the wake of war. Every increase in the amount or speed of intercourse between nations has increased the threat of exotic disease. Air transport has leveled further the barriers of time and space against many epidemic diseases which hitherto have been successfully excluded from vulnerable areas. Much of our foreign air transport now traverses fever- and mosquito-ridden areas. Many air fields are little more than runways hacked out of the jungle, with no opportunity for sanitation. The native laborers are reservoirs of strange infection and the insects are pestilent. Under the pressure of war schedules or actual combat, sickness or an insect vector often becomes a stow-away to the next landing place. Such may have influenced the recent outbreak of dengue in Hawaii, and the recent introduction of the *Anopheles gambiae* and the tsetse fly from Africa into the Western Hemisphere.

As our fighting forces have been dispersed over wider and wider areas, we have seen more clearly the need to organize our defenses in depth to protect the battle front and the home front.

Our first-line defense is the combined effort of the United Nations to protect in so far as is possible their military forces from the health hazards of global warfare. Our second defense is the active and coördinated quarantine barriers being set up by the Army, the Navy, and the Public Health Service. Our own civilian health services constitute our deep defense on the home front. The last is supported by biological and environmental factors here at home which give us the opportunity of confining to local outbreaks any infection which may slip through the lines.

Joint research to forge sharper

weapons has been expanded by the Army, Navy, and Public Health Service as an essential part of our strategy. Against malaria, for example, our weapons are not good. The search for more effective antimalarial drugs is urgent from the military point of view, because environmental control is impossible under combat conditions. Our knowledge of such exotic diseases as filariasis, schistosomiasis, and the leishmaniases is incomplete. These and many other problems of military significance are under constant study.

Last December, the President created the United States of America Typhus Commission, composed of officers of the Army, Navy, Public Health Service, and outside experts, and authorized it to study typhus fever and recommend measures for its control in any area affecting military personnel of the United States. The commission is now working in Africa and the Near East, in preparation for the huge typhus problem which is inevitable when our forces get into eastern or southeastern Europe.

Early in 1943, an Interdepartmental Quarantine Commission was set up to review and recommend changes in current laws and practices designed to prevent wartime spread of disease into this country or between military bases abroad. The commission is composed of medical officers of the Public Health Service, the Army, and the Navy, under the chairmanship of Assistant Surgeon General Dunnahoo. The commission has already completed a preliminary survey of the transmission of disease and disease vectors as a result of military operations, air transport, or surface travel. They are continuing their studies on several lines of communication east and west, and at foreign bases.

We shall have to reorient our quarantine strategy with regard to air transport, since long-range, land-based

planes nowadays fly in from distant ports and land deep in the interior. We shall need to set up quarantine stations at inland airports where foreign traffic is heavy, as we already have done at the Washington Airport, now a world air center. As a further check on the rapid dispersion of infectious diseases through the interior, however, airports of entry should be located as near to the coast as possible.

International agreements limit national quarantine measures to the control of smallpox, typhus, plague, cholera, yellow fever, leprosy, anthrax, and psittacosis. Little can be gained from increasing the list, especially if thereby quarantine regulations should be used as a means of setting up trade barriers inimical to post-war economic reconstruction. The perennial problem of quarantine versus commerce is the same now as it was in 1881 when the Secretary of State, in opening the first international health conference held in the United States of America, referred to "... this conflict between permanent, free, and open intercourse of trade, ... with this particular and pressing emergency of the public health." Quarantine, therefore, has been a sieve. It should not become a barrier in war or peace to necessary intercourse between nations. Its basic philosophy expressed in current military terms is that of "the calculated risk."

International barriers should not be set up against all infectious diseases. To do so would put into the hands of unscrupulous health officials punitive weapons against normal commerce. To overcome this tendency, there is general adherence to international conventions which limit quarantine jurisdiction to the most dangerous diseases. In this country we have successfully escaped imported epidemics of non-quarantinable diseases such as measles, dysentery, scarlet fever, and typhoid fever through good internal health de-

fenses, including the operation of interstate quarantine.

Circumstances of war may necessitate strengthening the federal interstate quarantine function, since the diseases which most concern the experts as potential post-war threats are not and should not be subject to national quarantine regulations. The Army and Navy may be relied upon not to release infected personnel until they have received the maximum benefit from modern treatment. However, some of the tropical diseases to which our troops have been exposed are not amenable to perfect medical control, and unpredictable relapses will occur.

Malaria is the outstanding example. Inevitably, malaria cases will be dispersed through the United States by returning troops. Local outbreaks are probable in parts of the country like the Upper Mississippi or the Hudson Valley, which have malaria mosquitoes, but which have been free from infection for many years. However, it is believed that history will repeat itself and that such outbreaks will die out, because, as in the past, the environment is not favorable to perpetuating the infection. But we should accelerate nature's process with mobile control forces to deal with outbreaks in any area. The triumvirate of modern malaria control is the physician, the engineer, and the entomologist. Equipped to analyze a situation from these three approaches, trained to organize effective control, these teams will be available to deal with any emergency outbreak, whether of malaria or other insect-borne disease.

Since the beginning of mobilization, the Public Health Service has maintained a mosquito-free zone around military and war industrial establishments in all malarious areas, building upon the work done during the depression years. As a total result, the Army experienced last year the lowest malaria rate in its history among troops

at home bases, although the bulk of them are in the South.

Yellow fever is a serious threat to all areas where the vector is present. The British, the Chinese, the Dutch are no less keenly aware than ourselves of the hazards to the Far East. Consider that one of our most important war air routes skirts areas in South America where yellow fever in the jungle form is endemic. It crosses tropical Africa, where yellow fever has been epidemic for years. And then the jump to India or on to China where teeming millions of people and the ubiquitous vector await only the virus to start a conflagration. One infected mosquito, one infectious case could light the fire of an epidemic far greater than those which flared in the United States during the last century.

Our troops are protected by improved vaccines, but it would be impossible to produce enough in time to protect whole civilian populations. There is not a port in the effective *ledecs* zone of the United States (below the southern boundary of Maryland) which is free of the yellow fever vector. We have begun control work at Miami, but we have a long way to go to equal the performance of Brazil where the yellow fever mosquito has been *eradicated* in every important port, and even in whole states.

As additional territory is conquered by our armed forces, urgent health problems will confront the occupying troops. Starvation and disease will be the two central facts. The control of epidemics will be a herculean task if the enemy wreaks the destruction in every city that he has done in Naples and on the Russian front.

For long months, intensive preparations have been made both by the military and by the Office of Foreign Relief and Rehabilitation to deal with anticipated problems. At the School for Military Government in Charlottes-

ville, for example, officers have been trained in problems of civil government, and the classes include a quota of Public Health Service officers, some of whom are now serving in Italy and North Africa.

Immediately after the OFRRO was created, Governor Lehman appointed a Health Advisory Committee composed of representatives from the government departments concerned and a few experts in international health problems. Coöperation was sought and gladly given by the Rockefeller Foundation and the Milbank Memorial Fund. All available epidemic and medical intelligence regarding each country has been pooled. Studies have been made of one country after another, embracing data on pre-war disease prevalence and distribution, sanitary and medical organization, number, size, and location of hospitals, health centers, laboratories, etc., the types of water supplies and methods of purification in each city, the estimated needs for medical and sanitary supplies, the number and location of camps for prisoners of war and political prisoners, the volume and nationality of slave labor, and estimates of the size and composition of the public health forces which will be needed.

When a country is reoccupied, there is an initial stage of military government. It may be assumed that as soon as the military situation permits, the government, while continuing under the general supervision of the theater commander, will be turned over to civilian auspices.

It has been announced that the United Nations and the nations associated with them in the war have been invited to sign an agreement in Washington on November 9, creating a United Nations Relief and Rehabilitation Administration. This will be the international agency through which public health control and other phases

of relief and rehabilitation will be carried on. In the proposed agreement, the second objective is to aid in the prevention of pestilence and in the recovery of the health of the people.

In any liberated country the basic policy will be to reconstruct the national health service as soon as possible. Outside aid obviously will be needed, but such aid will attempt from the beginning to work with and through the official national health departments and their local branches.

There has been joint planning between this country and other United Nations in connection with the problems of each occupied and enemy nation. In particular, representatives of the Inter-Allied Committee on Relief in London and our group on this side have exchanged full information concerning general plans. We have agreed upon standard lists and packages of medical and health supplies, and upon a procurement program to insure their availability. We have similarly agreed upon the size and composition of the public health and medical teams which will be needed. One unpredictable element in our planning is the future course of military events in a particular area—the amount of destruction and the further displacement of populations which will occur before final victory. It is gratifying to report that there is joint staff work and joint operational plans in the war against disease just as there is on global military strategy and operations.

Attention should be drawn also to the progress which has been made during the war in Pan American coöperation for stronger hemispheric health defense. This is being done through the Pan American Sanitary Bureau and through the Coördinator of Inter-American Affairs in coöperation with the health departments of the respective countries.

Of great importance, too, in future

global strategy against disease is the United Nations Organization on Food and Agriculture which will be set up following the recommendations of the Hot Springs Conference. In this organization, the improvement of human nutrition is a first objective. This international office of nutrition will be closely related on the one hand to health, and on the other, to agriculture.

Let me attempt to focus all I have said up to now and bring the several parts into relation with each other. We are faced with unprecedented health problems in this global war. On many sectors we have United Nations teamwork in dealing with wartime health problems. Further teamwork is assured especially in nutrition and in relief and rehabilitation.

But we need to look ahead a step further. We should begin now to plan with our allies a permanent international health organization ultimately to become world-wide in scope. After the war the needs for such an organization

will be greater than ever before. Air transportation will have broken down the barriers of time and distance. As a result of two world wars, we have learned that we cannot remain at peace with the rest of the world in flames. Similarly, I think, we cannot remain free from epidemic diseases if they rage in other lands. Moreover, improvement in health is the first step which needs to be assured in the backward nations if they are to attain a higher economic development.

International public health measures, therefore, should become the spearhead for peaceful international collaboration. Having learned to work and fight together to defeat the common enemy, we need equally to concert our efforts to the purposes of peace. The science of public health is the instrument through which much can be done to heal the wounds of war and to bring to mankind everywhere a new standard of healthful living which will surpass all previous human experience.

Public Health Implications of Tropical and Imported Diseases*

Yellow Fever and Typhus and the Possibility of Their Introduction into the United States

WILBUR A. SAWYER, M.D., F.A.P.H.A.

*Director of the International Health Division, The Rockefeller Foundation,
New York, N. Y.*

THE American health officer in this time of war is facing increased responsibilities with a diminished expert staff. He might possibly be interested in a lurid description of the havoc inflicted by exotic virus and rickettsial diseases on armies and populations in previous wars and in foreign lands, but I feel certain that he would prefer that I proceed at once to discuss the anticipated risk of the introduction of such diseases into the United States and the practical precautions that should be taken.

As for the common virus diseases, most of them are already widespread within our boundaries, and therefore outside the subject of this symposium. Smallpox, for example, is present where the laws requiring vaccination are inadequate or not enforced, and it is inconceivable that a partly vaccinated population could be endangered by the return of fully vaccinated soldiers from foreign countries. The occasional introduction of smallpox by civilians from abroad or its transfer from one state to another may occur in peace as well as in war, and serves to reveal which com-

munities are neglecting to keep themselves immune.

The pandemic of influenza during the first world war usually comes strongly to mind when war-engendered disease of virus origin is mentioned. There is no evidence to suggest that the appearance of this world-wide scourge had any relation to the war except coincidence. There is also no proof that the pandemic was due to a virus, as are influenzas A and B, although it would seem probable. It is hard to believe that any methods other than specific active immunization could protect adequately against the highly contagious influenzas. The most promising of the present vaccination methods still await field trial in the presence of an epidemic. We earnestly hope that we shall be spared the next visitation until the strain of this war on the people and their health departments is over and methods for producing active immunization against the known virus influenzas, and possibly applicable to pandemic influenza, have been made more effective and their results more lasting. In the meantime the state health departments can at least develop laboratory service in the field of virus diseases, as I have previously advocated before this organization,¹ and thereby become better prepared to assist in the

* Presented before a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

diagnosis of known virus diseases and to investigate the unknown.

YELLOW FEVER

Of the exotic virus diseases there is only one which needs special consideration—yellow fever. This tropical disease has been tricky and is still full of surprises. Time and again it has entered parts of the United States and has spread devastation until checked by cold weather. Its last visit was as recent as 1905 when it came to New Orleans, but nevertheless there is a tendency for health officers and the people generally to assume that the disease is a historic curiosity so far as this country is concerned, and will never return. Is it possible that the war situation will increase the risk of another introduction?

There seems to be no chance that smoldering infection will be fanned into flaming epidemics by the sending of our military personnel into the endemic areas of Africa and South America, or that members of the armed forces, returning while in the incubation period, will introduce the virus, inasmuch as all of those entering endemic areas are vaccinated against yellow fever. There are striking historical examples of extreme losses of men in military expeditions of non-immunes into the tropics, and yellow fever along with malaria and typhoid wrought havoc with our forces in Cuba during the Spanish-American war and the following period of military occupation. Fortunately a great mass of accurate and useful knowledge of yellow fever has been built up and published since then, beginning with the confirmation of Finlay's mosquito hypothesis by the United States Army Board in Cuba and leading up in steps to the discovery of the existence of jungle yellow fever, involving forest animals and new mosquito vectors,² and also to the devising and wide application of an effective method of vaccination.³

The discovery of jungle yellow fever put an increased emphasis on vaccination as a means of prevention, for the effective methods against the vector of the historic urban yellow fever, the domestic mosquito *Aedes aegypti*, could not be applied in the vast and almost uninhabited tropical forest. Accordingly vaccination is the sole reliance in fighting epidemic and endemic jungle yellow fever, and literally millions of persons have already been vaccinated. In some cases the purpose of vaccination is to protect travelers or military forces against expected exposure, and sometimes it is to stem the spread of an actual epidemic, but increasingly the intent is to immunize systematically as many inhabitants as possible in jungle yellow fever areas and especially around travel routes. This systematic vaccination prevents human infections which might occasionally introduce the disease into *aegypti*-infested towns and cause urban yellow fever capable of spreading through the channels of travel and trade. Barrier vaccination has also been practised. This consists in immunizing all the inhabitants in a zone between an area of jungle yellow fever and an uninfected region. The people around certain critical traffic points or seaports have likewise been vaccinated to lessen risks of spreading yellow fever. The urgent need for immunization of troops and civilians going to the endemic areas of Africa was emphasized in 1940 when the largest yellow fever epidemic ever recorded in that continent, with over 15,000 cases, occurred in natives of the Nuba Mountains, not very far from active theaters of war.⁴

If so much dependence is placed on vaccination, it is important to know the degree and duration of the immunity and the safety of the method. The vaccine now in use is essentially a strain of living yellow fever virus, derived from the original virulent Asibi strain from Africa and modified by prolonged

passage through tissue cultures. This strain, called 17D, has lost most of its viscerotropic and neurotropic virulence, while retaining a high degree of antigenicity. There are similarities between this vaccine and smallpox vaccine in efficiency and safety and probably in the duration of the immunity. While the degree of immunity, as measured by titration of antibody in the blood by means of mouse protection tests, tends to run down slowly with the passage of years, the recent Brazilian studies of Fox and Cabral,⁵ based on especially sensitive protection tests, and the field observations of Bugher⁶ in Colombia make it clear that most vaccinated persons remain immune for at least four years. This is not surprising considering the life-long immunity produced by the disease itself.

As for safety, the vaccine, made with a constant dried seed-virus tested by long experience and without the addition of any normal human serum, seems to be as innocuous as can be expected of any product containing living virus. Formerly, when a small quantity of human serum was being added in manufacture to help preserve the virus, a form of hepatitis resembling so-called catarrhal jaundice or common infective hepatitis appeared in many persons receiving certain lots of vaccine. In view of the reported appearance of the same phenomenon after injections of convalescent serum and transfusions⁷ it was concluded that this hepatitis was in all probability due to the chance introduction of an icterogenic agent, probably a virus, encountered occasionally in human serum. Fortunately it was found possible to substitute added chick embryo juice for the serum, and at present serum is entirely excluded from the vaccine in all the laboratories manufacturing it. Millions of doses of serum-free vaccine have been issued during the past year without reports of jaundice attributable to the vaccine or

other symptoms except the occasional malaise and slight rise of temperature frequently observed on the 6th or 7th day. This would seem to be the normal reaction.

The vaccine is not manufactured commercially anywhere, nor is it sent out to physicians. It is prepared in the United States in laboratories of the National Institute of Health in Montana and of the International Health Division of The Rockefeller Foundation in New York. Officers of the U. S. Public Health Service administer it without charge at a number of service stations to civilians who anticipate exposure in endemic areas. Distribution through ordinary channels is impracticable as there would be serious risk that the virus would die out and the vaccine become inert. The dried material must be kept cold and the re-dissolved vaccine must be injected immediately in accordance with the directions.

The most serious risk of introducing yellow fever is through air travel, and much is being done to control this situation. With travel time as a measure, the United States has been moved much nearer to the endemic areas in recent years and it would be quite possible for a person to be infected in the interior of Colombia, for example, and to reach the United States within the incubation period, or for an infected mosquito to make the trip. Geographically, yellow fever is not as near as it was early in this century, for recent surveys show that it is now absent from Mexico, Central America north of the Panama Canal, and the West Indies, although the infection is still present in the interior of Colombia and Venezuela and probably in Panama near Colombia, to mention only the nearest countries.^{8, 9, 10}

The risk of bringing yellow fever in has been greatly reduced in several ways. Travelers visiting infected re-

gions have been encouraged to get themselves vaccinated and to carry certificates which relieve them of certain restrictions on non-immunes. Passengers arriving from endemic areas are inspected by quarantine officers and their temperatures are taken. Persons showing elevation of temperature or other evidence of illness are detained until a diagnosis is made. Those who are well and are non-immunes, but who have possibly been exposed within a few days are kept under surveillance by the health authorities at the places of destination for the remainder of the incubation period of 6 days, unless the destination is north of any region in which aegypti might breed. As for mosquitoes, all airplanes from suspected areas are disinfected by spraying for the purpose of killing off all incoming insects, whether infected or not.

The remarks about our newest weapon against yellow fever do not imply that vaccination is a short cut in control which makes anti-mosquito work unnecessary. On the contrary, aegypti control remains the method of choice for cities and other places in the tropics and subtropics where this mosquito has become established. Aegypti is especially vulnerable, as it is highly domestic and accessible and not so widely distributed as is commonly supposed. This makes it possible for health departments to organize a systematic attack on the mosquito in its larval stages and so hasten this dangerous insect on the way to local extermination. The only limits are money, trained men, and the willingness of the public to allow complete periodic inspection of houses and premises. Most effective methods have been worked out in Brazil and applied with such success that in most cities and in many large areas *Aedes aegypti* can no longer be found. The methods used are being published in detail by Soper, Wilson, Servulo Lima, and Antunes,¹¹ and their

report will be made available by The Rockefeller Foundation to health officers specially interested. It was the successes in aegypti extermination that gave Soper and Wilson the confidence to undertake the complete extermination of *Anopheles gambiae* in Brazil.¹²

The control of jungle yellow fever in foreign endemic areas through vaccination and the elimination of the mosquito vector from seaports are really our first lines of defense, and we owe a debt of gratitude to those countries which maintain it. The quarantine precautions at our borders, including the disinsection of aircraft, and the immunization of travelers and airplane crews may be regarded as the second line. The third line of defense, and the one for which the responsibility rests on the local civilian health authorities, is the extermination of the domestic mosquito *Aedes aegypti* wherever it exists in the United States. General vaccination will be unnecessary in our civilian communities, since the measures here recommended are fully adequate. The suppression of aegypti can keep our communities non-infectible by yellow fever and also by that other aegypti-transmitted virus disease, dengue. Where dengue appears in our southern cities as occasional surprise epidemics, there yellow fever could also make its attack. Mosquito control is now well enough understood for it to seem inexcusable for communities to permit dengue outbreaks, just as in these times the presence of smallpox is looked upon as a sanitary disgrace.

TYPHUS FEVER

Of the rickettsial diseases, louse-borne typhus fever is the only one with a well earned reputation for spreading illness and death through troops and civilians in time of war. We can pass over the milder flea-borne typhus variant known as murine typhus, for it has long been endemic in the south-

eastern and southern states, where the scattered human cases are secondary to epizootics in rats. It is perhaps not impossible that, under war conditions far worse than any envisaged for the United States in the present conflict, this existing endemic human infection might become louse-borne and epidemic. Likewise we can disregard in this discussion the rickettsial tick-borne Rocky Mountain spotted fever, the very name of which is derived from its principal location in this country. Another disease caused by rickettsiae deserves a word in passing. The mite-borne scrub typhus or tsutsugamushi disease of the Far East has a geographic distribution which includes present theaters of war, but its introduction by returning troops and its establishment here with a suitable vector seem unlikely, if not impossible. More needs to be known of this scrub typhus situation and the possibilities.

Unlike yellow fever, louse-borne typhus is not inhibited by cold weather and is most prevalent in late winter and spring. The vector concerned is the body louse, and the scarcity of this insect in the United States under present conditions is one of the reasons for a feeling of security against any serious invasion by typhus fever. Nevertheless, there are in our large cities vagabonds and people living in poverty and crowded quarters who are louse-infested and necessitate constant vigilance to prevent the introduction of lice into cheap rooming houses and public hospitals. In the past the prevalence of body lice has been revealed on various occasions by the presence of typhus fever, as in certain labor camps to be mentioned later and in an Indian reservation.¹³ The head louse is still common but it plays at most only a minor rôle in typhus transmission.

The introduction of louse-borne typhus fever by returning troops would seem improbable. Even if louse-infes-

tation did become prevalent in overseas units of the armed forces as in the last World War, a happening which we are disinclined to predict in the light of the improved methods of delousing, and if some of the troops, although vaccinated, became infected abroad with typhus, the return of soldiers ill with typhus along with the vectors, in spite of the vigilance of the military medical officers and the quarantine authorities, is almost unthinkable.

There are, however, other ways in which louse-borne typhus can enter this country in time of war and spread as far as the local louse-infestation will permit. In fact, a case of the sort was observed in the Southwest in 1916, when I had opportunity to follow the events as Secretary of the California State Board of Health. The episode had a double war relation. Civil war in Mexico had brought widespread poverty and distress and had prepared the ground for the typhus epidemics which flourished in the highland cities and spread northward to the border states, involving both soldiers and civilians. To escape these conditions many of the poorer people emigrated to the United States, principally at El Paso, Del Rio and Laredo in Texas. On our side of the border the first World War was already having its effect, although the country had not yet formally entered the conflict. Unskilled labor was scarce and the railroads found that the Mexican peons were the only available supply. Laborers were recruited by employment agencies among the refugees, chiefly in El Paso, and were shipped with their typhus and their lice in many directions to primitive and insanitary labor camps along the railroad tracks. Scattered outbreaks appeared where these laborers went in Arizona, Colorado, California, Iowa, Illinois, and Central and Eastern Texas.^{14, 15} Some of the cases of typhus reported during 1916 and 1917

from New Mexico, Utah, Indiana, and Kansas may also have been produced in the same way. In Kansas the 2 cases reported were in a Mexican patient and a nurse in a railroad hospital.

In California typhus fever began to appear in the spring of 1916 in Mexican railroad section hands who had recently arrived. Although typhus fever had previously been practically unknown in the state, 31 cases were reported from June 1, 1916, to March 1, 1917, with 4 deaths. Of the first 26 cases investigated all except 2 were in railway employees, and all but 5 were in arrivals from Mexico. These 5 were classed as secondary,¹⁴ but the relationship to cases in Mexicans was not clear in every instance. An investigation of 44 of the camps in October showed an infestation with body lice of 35 per cent and with head lice of 60 per cent. The outbreaks were quickly controlled and the influx of typhus was checked by the detention and delousing of laborers entering the state in temporary observation camps, by sanitation of the section camps, with improvement of bathing facilities, and by the systematic delousing of infested laborers at the Mexican border by the U. S. Public Health Service and within the state by the railroads under regulations of the State Board of Health. Since then, however, typhus fever, now classed as endemic and probably of the flea-borne murine type, although the 1916 outbreak was undoubtedly louse-borne, has been continuously present in California. There were waves of increased incidence from 1921 to 1924 and from 1936 to 1942, and according to Halverson¹⁷ the total number of cases up to 1942 reached 229.

The experience in Iowa was reported by Boyd.¹⁸ A louse-infested Mexican laborer who had been brought from El Paso about 7 days before and who had been out of Mexico for 2 months, was admitted to the railroad hospital in

Fort Madison. From this patient typhus fever was contracted by the doctor who examined him, the nurse who took charge of his clothing, the male nurse who undressed and bathed him, a Mexican laborer who visited him before the diagnosis was made, and another Mexican laborer who shared his hospital room. A male nurse who was present when the last mentioned patient was deloused also contracted the disease. The 8th and last in this series of typhus cases was in a Mexican laborer admitted to the same hospital from Surrey, Ill., where he had been in contact with another Mexican laborer who had been in the Fort Madison hospital while the previous cases were there.

The present situation in the United States with respect to the risks of typhus introduction is quite different from the one in 1916. Mexico is free from civil war and there are no extensive typhus epidemics in that country, although the louse-borne disease is present. In this country, however, there are labor shortages on account of the war, much movement of people, and acute housing deficiency and crowding around war plants. The protection of civilians against introduced louse-borne typhus requires, as in the case of yellow fever, that every community be kept non-infectible. General vaccination of population groups would not be justified with the present low risk of exposure and would be less dependable than louse control. Adequate insurance against typhus epidemics must depend primarily on the destruction of the vector.

If a domestic mosquito like *Aedes aegypti* can be locally exterminated by organized inspection and the destruction of larvae, how much simpler it would be to exterminate the body louse, which is more than domestic—even strictly personal. The health officer with a louse infestation problem in a

civilian population needs effective methods for systematic inspection to establish infestation rates and check on results and also some simple and inexpensive way to free clothing of lice. Such methods are being devised and tried out and should in due time become generally available. There are two important elements in the methods giving the most promise for civilian use. They are, first, a highly insecticidal powder which is not toxic when in long contact with the human skin and, second, a system and organization for seeing that the powder is thoroughly applied to the clothing at regular intervals and for keeping close track of the degree of infestation. Satisfactory results have been obtained by Davis and Wheeler¹⁹ with certain of the newer powders in delousing volunteers in a road builders' camp in New Hampshire after artificial infestation. A field study in five naturally infested Mexican villages was carried out by Davis, Malo Juvera, and Hernandez Lira²⁰ for the purpose of finding methods for ridding an entire town of lice cheaply, rapidly, and with a minimum of equipment. Powders were used to kill lice in the clothes, and a lotion to destroy those in the hair. In one of the towns typhus was present. Following treatment the disease disappeared and the number of persons with lice approached zero in the second week. It was evident that administrative measures and insecticides were at hand which, after perfection of details, could be depended upon by the health organization to keep people free of lice and consequently non-infectible by louse-borne typhus fever. It seems now that periodic disinfestation with elaborate equipment followed by prompt reinfestation may soon give way to effective methods for keeping the community continuously free of lice by locally exterminating them and by the same measures making reinfestation impossible.

The described episode during the last World War indicates that all that protected us from a widespread epidemic of typhus fever was the general freedom of the public from body lice. As a rule the disease showed no tendency to spread beyond the immediate contacts of the persons introducing it into the communities. There is no reason to believe that lousiness is any more prevalent now than then or that there is serious danger that anticipated war conditions here will bring about a great increase in these insects. Nevertheless, as a precaution, it is incumbent on health officials to search out and remove the few existing foci and thus give protection against the spread of epidemics of typhus either from introduced louse-borne disease or from the existing endemic foci of the murine variety.

The health officer is now in a position to remove all danger of the invasion of his community by yellow fever or louse-borne typhus by keeping it non-infectible in peace time and even during the risks and difficulties imposed by war.

Public Health Implications of Tropical and Imported Diseases^{*}

Imported Malaria

MAJOR O. R. McCOY, M.C., AUS

Tropical Disease Control Section, Division of Preventive Medicine, Office of the Surgeon General, U. S. Army, Washington, D. C.

MALARIA has been by far the major medical problem encountered by the Army overseas. The campaigns in New Guinea, the Solomons, and southern Italy are being fought in some of the most malarious regions of the world. In addition, many troops are stationed in or travel through such malarious regions as tropical America, equatorial Africa and India. As a consequence, large numbers of our troops are being infected with malaria. Even with proper treatment relapses of the disease are frequent and periods of latency may persist for months. In many malarious areas troops are given suppressive treatment with atabrine. In some of these individuals, initial clinical attacks may not appear until many weeks after medication is stopped. It appears inevitable that large numbers of our troops will be returned to this country infected with malaria. During the current year approximately 65 per cent of the cases of malaria reported in the Army in this country were acquired abroad. The number of cases in men returned from overseas may be expected to increase as the war progresses and, of course, will be greatly multiplied when the fighting ends and

our armies are brought home to be demobilized.

The question arises as to what influence this influx of cases from abroad will have upon the malaria situation in this country. In the past the area of endemic malaria extended widely through the northern states. Although in recent years the area of endemicity has shrunk greatly, the potentiality for the re-introduction of the disease still exists in many parts of the country. Potential anopheline vectors of malaria are to be found in every state of the Union. In some areas, at present malaria-free, *Anopheles quadrimaculatus* may be quite numerous during the summer season. The chief problems of public health concern related to the return of cases of malaria from abroad may be summarized as:

1. The possibility of establishing new endemic foci of the disease in areas now free from malaria.
2. The introduction of new strains of the parasite in regions where malaria is already present, and a resultant increase in the amount of malaria in these areas.
3. Prompt recognition and proper treatment of relapses in soldiers after they have returned home on sick leave or furlough or have been discharged from the Army.

The first of these problems, the possible establishment of new endemic foci, has attracted the most attention. Exaggerated statements predicting dire

^{*} Presented before a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

consequences have occasionally been published in the public press. Suggestions have been offered that troops returned from malarious areas should be segregated. In the North the point of view is that such troops should not be sent to northern states because these sections—malarious 100 years ago—are now free from malaria and it should not be introduced again. In the South the opinion prevails that infected troops should not be brought to southern states because in this part of the country conditions are most favorable for the spread of the disease. There is some merit in both points of view, but question may be raised as to whether either is really necessary.

The practical difficulties of segregation are, of course, obvious. At present there are no certain criteria by which a case of malaria may be pronounced completely cured. Relapses may occur after many months of latency. It would certainly be impractical to attempt to deny furlough to returned soldiers for any such length of time.

Since the discovery of the mosquito transmission of malaria at the turn of the century, it has been demonstrated repeatedly that the most fruitful methods of malaria control are those directed against the mosquito vector. Methods designed to control the human reservoir of the disease are of decidedly lesser importance. In this country the accepted line of attack against malaria has been that against the mosquito vector. No attempt has been made to control the movement of human carriers of the disease. Up until the last decade thousands of infected immigrants from southern Europe were allowed to enter this country and to settle at will. Seasonal migration of southern agricultural workers to northern states has been encouraged. No untoward consequences in the malaria situation have resulted from this policy.

There seems no good reason to take a different attitude toward soldiers who may be carriers.

Three years ago when the country began to rearm, steps were taken to deal with malaria at the large training camps in the southern states. It was decided that the Army would conduct mosquito control within the boundaries of military reservations and that the U. S. Public Health Service would carry out control measures, when necessary, in a mile-wide zone surrounding the reservations. This plan was originally instituted to protect soldiers at military camps from acquiring malaria from civilians. But these precautions can also work the other way around—to help prevent spread of malaria from soldiers to civilians. For instance, certain Army general hospitals in malaria-free areas have recently received considerable numbers of cases of malaria from abroad. Concern was felt regarding the possible spread of the disease to surrounding communities. The organization for the Control of Malaria in War Areas, of the U. S. Public Health Service, has made mosquito surveys at such hospitals and has instituted control measures when indicated. Since many cases of relapsing malaria have occurred among prisoners of war, the same precautions are being taken in respect to internment camps. The effectiveness of control among troops in the continental United States is well illustrated by a comparison of the malaria rates in this war with those of the last war (Figure 1).

As long as soldiers remain under military control there should be slight chance of spread of malaria to civilian communities. The men live in well sanitized camps. When sick, they receive prompt medical attention. Proper screening of hospitals should prevent them from being bitten by mosquitoes during periods when gametocytes are most numerous in the blood.

U. S. DIV. OF PREV. MED.

The chief problem arises after soldiers have been discharged from the Army or return home on sick leave or furlough. When relapse cases occur in communities where there are anopheline mosquitoes these individuals may be a source of spread to others. It is well to consider how serious this danger is apt to be.

Outbreaks of malaria have occurred from time to time in nonendemic areas in the northern United States. In recent years there have been such outbreaks in southern Minnesota, eastern Iowa, northern Ohio, and in Camden, N. J. In the summer of 1943, an outbreak of 53 cases occurred at a small town in Illinois. The characteristics of these outbreaks are much the same. They have involved comparatively few cases, they have not tended to spread, and often have subsided without anti-mosquito measures. Unlike dengue, malaria does not tend to occur as an explosive epidemic. Even in localities where conditions are favorable for spread, the warning given by prompt

recognition of early cases ought to allow the institution of control measures to prevent an extensive epidemic. It would appear reasonably certain that prompt action to control *Anopheles* mosquitoes will be sufficient to prevent serious trouble from any new foci of malaria which may occur. Where local authorities do not have the personnel, supplies, or equipment to conduct anti-mosquito work, the U. S. Public Health Service with its special organization for malaria control is prepared to give immediate help when asked to do so by the state department of health.

The second main problem to be considered is the introduction of new strains of malarial parasites in the present areas of endemicity. Undoubtedly this will happen. It is well known that inhabitants of endemic malarial regions acquire immunity to local strains but have little or no immunity against new strains introduced from other regions. The most feasible solution for this problem would seem to be an intensification of mosquito control

in the known endemic regions in this country. This procedure has the advantage of helping to reduce the amount of malaria already present, as well as to guard against any danger from the introduction of new strains. During the past few years malaria rates in the South have been the lowest ever recorded. Special efforts for mosquito control at this time might reasonably be expected to decrease and perhaps eliminate many areas of endemicity.

Another aspect of the general problem is the possibility that new strains of malaria introduced might be more virulent than those already present in this country. Although differences in virulence may occur, they apparently are not of sufficient magnitude to be of great significance. In recorded epidemics of malaria it has almost always been some change in the mosquito population that has been responsible. For example, in Brazil some years ago it was the introduction of a new vector, *Anopheles gambiae*, which is a more dangerous carrier than the species of anophelines normally present. In the Ceylon epidemic ten years ago it was the exceptionally great increase in the number of anophelines already present.

Over 90 per cent of the relapsing cases of malaria among returned troops are of the *vivax*, or tertian type. This species of parasite is much less apt to produce malignant infections than is *Plasmodium falciparum*, the subtertian or estivo-autumnal parasite which predominates in the tropics. Although it is more difficult to effect a permanent cure of *P. vivax* infections, this species can be considered less dangerous than *P. falciparum* as far as introduction into this country is concerned. In the past the most serious epidemics of malaria have always been caused by the *falciparum* parasite.

Probably the most important problem connected with the return of infected troops has to do with the individual

soldier himself. Will there always be prompt recognition of malaria relapses in soldiers after they have returned to their home communities? In many sections of the North, physicians are not familiar with malaria, especially the estivo-autumnal type caused by *Plasmodium falciparum*. Failure to make a prompt diagnosis may be a serious matter in cases of malignant malaria. Prompt diagnosis of malaria cases is not only important to the patient but is also important for the timely institution of control measures if outbreaks of malaria should occur.

A program of education is needed to give practising physicians better knowledge of the diagnosis and treatment of malaria and other tropical diseases. Laboratory workers in many places require greater experience in the recognition of malaria parasites, and especially need training in the use of the thick film technic of diagnosis. Programs of special lectures and symposia on tropical medicine arranged by state and county medical societies will serve a useful purpose. Instructional articles in society journals, especially those local journals which usually reach every doctor in the community, may also be a helpful means of education. Many of the doctors now serving in our armed forces are acquiring extensive experience with tropical diseases. The return of these doctors to their home communities ought to exert a favorable influence on the practice of tropical medicine in this country.

DISCUSSION

During 1943, the majority of troops coming back to this country with malaria have been returned as patients. Most of them remain in military service. Comparatively few are permanently discharged. As already pointed out, the chief danger of spread of malaria from soldiers is after they have returned home. The time of the greatest hazard

will not come until after general demobilization. It may be expected that the demobilization of large-sized units will require a certain amount of time, some weeks at least. This will allow discovery of a considerable percentages of relapsing cases of malaria, particularly among those who have recently been taking suppressive treatment. It is possible that a serological test, such as the complement-fixation test, may be developed to the point where it can be profitably employed to screen out infected individuals who would be subject to relapse. If this is done, however, the question would still remain as to how long these individuals should be kept under surveillance. At present there is no drug which is effective in curing latent cases. The discovery of such a drug would, of course, greatly simplify the whole problem.

Both the Army and the Navy are fully aware of their responsibilities in helping to prevent the spread of malaria by returning military personnel. Both services are maintaining close co-operation with the U. S. Public Health

Service in considering proper means for dealing with the problem.

SUMMARY

Large numbers of troops returned from overseas are infected with malaria. At present more than 90 per cent of cases are relapses of the *vivax*, or tertian type. Although there is a hazard of the establishment of new foci of malaria in sections of the country now free from the disease, the chances of serious consequences from such introduction are not considered very great. Prompt antimosquito measures should bring about rapid control of possible outbreaks. Intensification of anopheline mosquito control is indicated in the present endemic areas in this country to lessen the hazard from the introduction of new strains of malarial parasites. The most important problem connected with the return of military personnel infected with malaria is to insure proper diagnosis and treatment of the relapses which may occur after the service men have returned to their home communities.

Public Health Implications of Tropical and Imported Diseases*

Public Health Aspects of Certain Other Diseases to Which Our
Military Forces May Be Exposed

HENRY E. MELENEY, M.D., F.A.P.H.A.

*Hermann M. Biggs Professor of Preventive Medicine, College of Medicine,
New York University, New York, N. Y.*

THE title of this paper is purposely vague in order to afford an opportunity for a brief but broad survey of the diseases to which our military forces may be exposed in the world-wide conflict in which they are engaged. The world picture of the present distribution of our forces shows that they are in contact with native populations and pathogenic fauna and flora from the Arctic through the tropics of both hemispheres, and to the south temperate zone of the eastern hemisphere. Furthermore, the massing of large bodies of men in close contact with each other favors the spread among them of infections acquired from native populations.

The preceding papers in this symposium have dealt with three of the most important diseases to which our military forces are or may be exposed. It is the province of this paper to present briefly the degree of danger of importation of other so-called tropical diseases and parasitic infections, and the likelihood of their spreading and becoming endemic in this country. The chances of introduction and establishment of exotic diseases depends upon several factors. Acute diseases having a relatively short period of communica-

bility are much less likely to be introduced than diseases of a chronic nature or long incubation period. Diseases requiring a specific intermediate host may be introduced but cannot become endemic unless favorable intermediate hosts are present or are introduced and become established. Carriers of cosmopolitan diseases may attain a high incidence in large bodies of troops and cause an increased incidence when demobilization brings them in contact with our civilian population. It is conceivable that strains of certain microorganisms with a higher degree of pathogenicity acquired abroad might produce more severe disease in the civilian population if transmission occurs. A few diseases already endemic in this country in localized areas may become more widely distributed by the dispersal of troops from the endemic areas to their homes.

From these generalities let us first consider the diseases of high incidence in other parts of the world which by their nature are least likely to present public health problems in this country. The acute diseases in this group beside those already considered in this symposium are plague, cholera, dengue fever, and phlebotomus fever. We already have a plague problem in this country in the wild rodents of the

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

western states which is of considerable concern to our public health authorities, but the war should have little effect on this problem. We have a moderately protective vaccine for use in our forces which may be exposed to the disease abroad, and there should not be any new introduction of infected rats to port cities unless some disaster breaks down our highly efficient inspection of ships.

We also have a moderately effective vaccine against cholera, which will be used in the event of probable exposure of military personnel. With the advance of our forces into the endemic area of Burma, where the bombing of cities and the retreat of the enemy may lead to native epidemics, cases may occur in our advancing troops, and it is conceivable but improbable that a few carriers of the vibrio might harbor it until they return to this country. Such a possibility is mentioned only to keep it in mind.

Dengue fever is endemic not only in the eastern hemisphere but in the American tropics. It may cause disabling epidemics in the armed forces to the detriment of military progress. Owing to its short period of communicability it will probably be introduced again into the United States only from nearby Latin America. The threat of future epidemics in our southern states will not be removed until we accomplish the eradication of the mosquito vector, *Aedes aegypti*, as our neighbors in Brazil have done.

Phlebotomus fever, another disabling disease of very short duration, is not likely to be introduced into this country because the phlebotomus fly occurs here in only a few limited areas, and its breeding habits and short range of flight make the importation of new species a practical impossibility.

The chronic diseases which are not now endemic in this country or are present only in limited areas, and which are not likely to spread or become en-

demic, include a wide range of bacterial, spirochetal, protozoan and helminth infections.

Leprosy, endemic in restricted areas of Louisiana, Texas, and Florida, still presents a minor epidemiological problem, but probably will never spread beyond its present confines. A few infections may be expected to occur in individuals who come into unduly intimate contact with natives in the Orient, and these may develop clinical manifestations years after they return home. Past experience indicates that such cases will not give rise to others in this country.

Yaws, another disease transmitted by intimate contact, should not be expected to appear in our military forces, but if it does it will undoubtedly be recognized and cured where it occurs.

The chronic protozoan diseases, aside from malaria and amebiasis, are caused by the blood flagellates—*Leishmania* and the trypanosomes. The leishmanias are transmitted by phlebotomus flies. The visceral disease, kala-azar, is endemic in the Mediterranean littoral, the Sudan, northeastern India, northern China, and northeastern Brazil. The Old World cutaneous form is endemic in northern Africa and the Near East as far as northwestern India. The New World cutaneous form is endemic in the northern half of South America, Central America, and some of the West Indies. A few cases of all three forms may occur in the armed forces, but will present only problems of diagnosis and treatment. They cannot become endemic in this country in the absence of the vector.

African trypanosomiasis, caused by *Trypanosoma gambiense*, occurs in that part of equatorial Africa where American and Allied forces have been stationed, and along routes of air transport. Isolated cases may occur in our troops and may not develop clinical symptoms until they return to this country. The

tsetse fly vector does not at present occur outside of Africa, but two specimens have been found in commercial airplanes reaching Brazil from Africa.¹ This indicates the necessity for rigid inspection and thorough spraying of both military and commercial planes after intercontinental flights, even though it would require a peculiarly favorable combination of circumstances to establish both the fly and the disease in the American tropics.

A few cases of American trypanosomiasis, caused by *Trypanosoma cruzi*, may occur among our troops stationed in South or Central America, but the infection is usually subclinical or mild in adults. It is already present in certain wild rodents and cone-nosed bugs in California, Arizona, and Texas, though no naturally infected human cases have yet been found in this country. One human case, produced experimentally from a naturally infected bug in Texas has recently been reported,² indicating that naturally infected human cases may occur. It is not likely, however, to become a serious problem.

Many helminthic infections of great clinical importance in extensive or restricted areas of the world may be encountered by our military personnel. Most of these are likely to produce only sporadic cases which will be problems of diagnosis and treatment, though subclinical cases may return to this country and raise the question as to whether the disease may become endemic.

Among the trematodes, the schistosomes are the most important. They infect man by penetration of the larvae through the skin after immersion in water containing infected snails. Individual infections may be acquired by bathing in or wading, fully clothed, through infected streams or ponds, or even from infected water piped to camps for bathing purposes without adequate chlorination. It is reported by a Ger-

man investigator³ that the usual sand filtration of water will not remove the larval forms. It is conceivable that our troops campaigning in the Celebes or Central China may become infected from immersion in streams, lakes, or canals. There is great specificity of the snail intermediate hosts of these worms and it is not known whether species which could act as intermediate hosts exist in the United States. The possibility, however, is indicated by the fact that schistosomes of lower animals, whose larvae give rise to an acute dermatitis in man, are endemic in this country, and research is desirable to determine whether possible intermediate hosts of human schistosomes are also present. The importation of farm labor into this country from endemic areas of *S. mansoni* in Puerto Rico and other West Indian islands emphasizes the desirability of such studies.

The other trematode infections of man are acquired by eating raw fish, crustaceans or water plants, and should not be encountered in our military forces.

Among the tapeworms there are only three to be considered. *Taenia solium*, the pork tapeworm, is practically unknown in this country. It may be acquired by eating insufficiently cooked native pork in regions where medical inspection is not required. Its importance is mainly clinical, because the larval stage may develop in man, causing fatal infestation of the brain.

Echinococcus, the dog tapeworm, which produces larval cysts in man, is a common human infection in northern and southern Africa, the Near East, and Australasia. In Iceland strict control measures have reduced the formerly high incidence. Man becomes infected from close association with dogs. It is possible that a few infections may be acquired by our military forces. In certain parts of the United States the infection is common in hogs, but for

some unexplained reason is uncommon in man. It is not likely to become a human problem in this country.

Diphyllobothrium, the broad fish tapeworm, is acquired only by eating certain insufficiently cooked fresh-water fish. It is widely endemic in Europe and Asia but its method of transmission limits it to certain racial and religious groups. It is already endemic in our north central states, and a recent report indicates a possible endemic focus in Florida.⁴ It is improbable that new infections will be introduced by returning troops.

Among the intestinal nematodes, hookworm is the only important infection to be considered. Since our troops are not likely to go barefoot even in the jungle, the only possibility of their acquiring the infection is by lying, insufficiently clothed, in infected soil during active campaigns. Although the hookworm in this country has been attacked rather tardily in some of the heavily endemic areas, the prospect of reducing it to negligible proportions should follow continuation of vigorous control measures in the post-war period.

Lymphatic filariasis, caused by *Wuchereria bancrofti*, is the chief nematode problem facing the armed forces at the present time. The infection has a practically world-wide, though spotty, distribution in the tropics, and is particularly prevalent in native populations in the East Indies and parts of southern Asia. A considerable number of infections have already occurred among military personnel quartered close to native populations in the Pacific Islands. Repeated infection is required to produce elephantiasis or other permanent deformities, and the female worms require about a year to become adult and begin discharging larvae into the lymphatics and blood stream. The first symptom of infection, however, is acute localized lymphangitis, beginning about 6

months after infection when the worms are still immature. The cause of the lymphangitis is still in doubt, but it incapacitates the patient for days or weeks and usually recurs at frequent intervals for months or years. Since the disease is transmitted by a variety of mosquitoes, the chief of which are the common night-biting *Culex* species of world-wide distribution, breeding close to human habitations, prevention of infection has made little advance in most endemic areas. In the United States the only endemic area has been in and about Charleston, S. C., but a recent report⁵ indicates that the parasite may have disappeared from this area. Since heavy infections and massive exposure to mosquitoes are necessary to establish and maintain an endemic area, it is highly improbable that returning troops will create any new foci in this country. The problem in the military personnel is primarily one of treatment of the recurring lymphangitis. No effective chemotherapeutic agent has yet been discovered, but it is hoped that research now under way will produce a cure for this disabling disease.

Bacillary dysentery is of great concern to military forces, not only in the tropics, but in temperate zones. It was a scourge in every war in which this country has been engaged until the first World War, and even then severe epidemics occurred in the American Expeditionary Force in France, and it was the commonest cause of illness in non-combatant troops stationed in the Philippines. It was a severe handicap to the military operations of the British in southeastern Europe and the Near East. In the present war it has caused epidemics in army camps in this country and has had a high incidence among British troops in the North African campaign. Whenever epidemics occur, a high incidence of symptomless carriers of dysentery bacilli can be found

in contacts living under the same conditions as the cases. A small proportion of cases and symptomless carriers become chronic carriers and give rise to future spread. Although an apparently protective toxoid has been prepared from the soluble toxin of the Shiga strain,⁶ this will probably be effective only against Shiga infections, and no protection can be expected against the Flexner and other strains of the organism. Protection of the military forces must depend entirely upon sanitary food handling and excreta disposal, safe water supplies, and control of flies. Individual instruction of troops and enforcement of sanitary discipline, though difficult, must become a part of military operations. The great effectiveness of the sulfonamide drugs in the treatment of bacillary dysentery should reduce the number of chronic cases and carriers. These drugs can also be used in smaller doses for the prevention of active cases among contact carriers in the presence of an epidemic. This has already been demonstrated in mental hospitals as well as in a military unit.⁷ The only possible danger of spreading the disease in this country from returning military personnel would be from the introduction of highly pathogenic strains which might be transmitted to families, institutions, or military camps in the presence of bad conditions of sanitation or personal hygiene.

Amebiasis, of which amebic dysentery and liver abscess are relatively infrequent clinical manifestations, is also a cosmopolitan infection widely prevalent in this country, but giving rise to more frequent and severe symptoms in many tropical and unsanitated regions. Recent experiments indicate that the cysts of *Endamoeba histolytica* are not all destroyed by the concentration of chlorine ordinarily employed for the production of potable water,⁸ and that insufficient depth of sand and too rapid filtration in mechanical filters may allow

cysts to pass through. The opportunities for drinking contaminated water in forward military zones, as well as the contamination of vegetables, the presence of flies, and exposure to native food handlers in most tropical areas, greatly increases the chances of infection of military personnel. Although reports indicate that amebic dysentery and liver abscess have not thus far occurred with great frequency among our forces at home or abroad, circumstances in newly invaded areas may cause the disease to become more important. There is good evidence that strains of *Endamoeba histolytica* differ in the frequency with which they produce clinical symptoms and in the severity of the symptoms, and that highly pathogenic strains are more common in certain areas or in epidemics such as that in Chicago in 1933.⁹ For this reason the introduction of strains from the tropics must be considered a potential hazard. Moreover, this infection often has an extremely long incubation period, or may become chronic in unrecognized or insufficiently treated cases, thus exposing families or larger groups under circumstances of defective sanitation. In the protection of our forces from amebiasis the same rigorous discipline is necessary as for the prevention of bacillary dysentery, with the additional requirement that improved methods are necessary for the elimination of cysts from military water supplies in forward areas.

Typhoid fever fortunately presents no great problem to the military forces owing to the efficacy of the vaccine. Although a few cases will almost certainly occur from insufficient protection against massive infections, it is not likely that a sufficient number of carriers will be produced to create a hazard from returning personnel.

There remains one fungus infection endemic in this country, but rarely encountered elsewhere, which deserves

brief consideration. This is coccidioidomycosis which is endemic in California, particularly in the San Joaquin Valley, and in Arizona and Texas.¹⁰ Since infection is usually acquired by the inhalation of dust in dry, sandy regions, military forces training in endemic areas are exposed to infection.¹¹ Fortunately, many infected persons seem to develop immunity without clinical symptoms, and the primary clinical infection in the lungs usually resolves permanently without the later general dissemination which is often fatal. The possibility of a rodent reservoir of this infection and the ability of the fungus to survive in a dry state make prevention a difficult problem for those who reside in endemic areas. It would seem wise for the military forces to determine whether or not the infection is present before establishing training areas in arid regions, and to remove installations which have already been established in infected areas. Fortunately it is probable that this fungus cannot be disseminated easily except in dry regions, and it is improbable that it will extend much beyond its present confines unless it is carried by dust storms, vehicles, or rodent reservoirs. Since transmission from man to man has not been observed, it is practically impossible for the infection to be transported by our military forces to other countries.

SUMMARY

A review of the diseases to which our military forces may be exposed in the present world conflict indicates that very few diseases of foreign origin are likely to present public health problems as the result of infections introduced by returning troops. A few cases of acute or chronic diseases such as plague, cholera, leprosy, yaws, leishmaniasis, trypanosomiasis, schistosomiasis, or other helminth infections may occur among troops coming into close contact

with native populations. Dengue and phlebotomus fever may cause brief but incapacitating epidemics. Filariasis may incapacitate a considerable number for future military service in the tropics, but is not likely to develop new endemic areas in this country. Bacillary dysentery is a constant threat to effective military operations, and its prevention requires strict military and sanitary discipline. The only danger to this country from bacillary dysentery and amebiasis is the possibility of the introduction of new strains of organisms which might give rise to more serious infections in our civilian population. The fungus infection coccidioidomycosis, endemic in certain arid regions of our western states, presents an immediate problem of infection in troops under training, but is unlikely to become a problem of civilian populations very far outside of its present endemic areas. In short it may be stated with considerable confidence that the chief hazards in the importation of exotic diseases are from the introduction of new strains of parasites already present, and the introduction of new vectors of disease. The Army, Navy, Public Health Service, and the medical schools have instituted better instruction in tropical medicine, and thousands of medical officers are gaining practical experience with the armed forces. Through a better understanding of tropical medicine by the medical profession, by the expert training of laboratory personnel, and by the continued development of alert national, state, and local public health services, there is little danger that the present war will result in the serious dissemination in this country of diseases which would not occur in times of peace.

Symposium on Cancer Regarded as Successful

Morton L. Levin, M.D., the Assistant Director of the New York State Division of Cancer Control, Albany, who is serving as Secretary of the Cancer Symposium Committee, reports that the Cancer Symposium arranged at the 72nd Annual Meeting of the American Public Health Association by an informal group attracted an attendance of more than 300 persons on October 11. According to Dr. Levin, at least 16 states and 45 institutions or organizations were represented.

An informal Cancer Committee was reappointed by the group following the meeting, composed of the following persons:

Herbert L. Lombard, M.D., *Chairman*
 Morton L. Levin, M.D., *Secretary*
 Lauren V. Ackerman, M.D.
 Raymond V. Brokaw, M.D.
 Thomas J. Duffield
 James W. Hawkins, M.D.
 Clarence C. Little, Sc.D.
 J. Louis Neff
 Edmund Zimmerer, M.D.

Immunizations in the United States Army

LT. COLONEL ARTHUR P. LONG, M.C.

*Preventive Medicine Service, Office of the Surgeon General, U. S. Army,
Washington, D. C.*

INFECTIOUS diseases have always played a significant rôle in the prosecution of wars. Such diseases have, in all major conflicts of the past, been responsible for more deaths and disabilities than have the injuries of battle. In reading the histories of our past campaigns, it is gratifying to note that there has been a progressive improvement in the care afforded the sick and wounded. Improvement in the effectiveness of measures designed to prevent diseases have, however, developed somewhat more slowly. In the Mexican War, disease caused seven times as many deaths as did battle. In the Civil War, the ratio was about two deaths from disease to one from battle injuries. At the time of the Spanish-American War, while information was available about many of the micro-organisms of disease, military sanitation and hygiene were as yet not well developed. Consequently, again seven men were lost from disease to every one killed in battle. One of every five men developed typhoid fever, and this disease, now fortunately largely preventable, resulted in 80 per cent of the total deaths.

During World War I, the advances that had been made in the control of infectious diseases were applied effectively in military preventive medicine.

During that great war, the number of men lost from battle injuries and those dying from disease were almost equal. The major problems were those presented by the respiratory diseases, particularly influenza.

The problems of disease prevention in the present war are undoubtedly the greatest with which our Army has ever been confronted. With what success these problems will be met is impossible to say at this early date. The record up to this time is good.¹ It is sincerely hoped that this record can be maintained and improved. To this end, every effort is being made by the Medical Department to apply effectively the best methods and procedures for the prevention and treatment of disease.

In this discussion, only one aspect of these activities will be considered—the prevention of disease by means of immunization. The regular immunization procedures available for troops during the last war were essentially limited to vaccination against small-pox, typhoid fever, and the paratyphoid fevers. Today there are six active immunizations which are being administered more or less routinely, and other procedures which may be used under certain circumstances.

For administrative purposes, these immunizations have been divided into two classifications: the so-called "routine" immunizations, and the "special" immunizations.

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

ROUTINE IMMUNIZATIONS

The routine immunizations are those administered to all military personnel as soon as possible after entrance into the federal service. These are vaccinations against smallpox, typhoid fever, and the paratyphoid fevers, and active immunization against tetanus.

SMALLPOX VACCINATION

Smallpox vaccination was, of course, the first immunization to be practised in the United States Army. It was used on a small scale during the War of 1812 and the Mexican War, and somewhat more extensively during the Civil War. Universal vaccination of troops was adopted in our Army at the end of the last century. Since that time, vaccination of all military personnel has been rigidly enforced and the occurrence of smallpox is so rare as to be almost nonexistent. This is not surprising. It is merely another example of the results of complete vaccination of a population and serves to emphasize once again that epidemics of smallpox need not occur.

Glycerinated calf dermo vaccine is the agent utilized for smallpox vaccination. The method recommended is that commonly known as the multiple pressure method, and, of course, the use of dressings of any kind over the vaccinated area is avoided. Smallpox vaccination is repeated every 3 years unless it is known that there has been exposure to cases of the disease or that such exposure is likely to occur. In these instances, it is considered more practical to vaccinate all of the contacts than to attempt any sort of selective vaccination.

Occasionally the question is asked as to whether or not the possible exposure of troops to highly virulent forms of smallpox will require their vaccination with a more potent strain of vaccinia virus than that commonly used. This is not considered to be necessary. It is believed that adequate protection can be

afforded by the maintenance of a high level of immunity through frequent vaccinations. In this connection, it is important to recognize that a primary type of reaction is not necessary for the stimulation of immunity. An increase in the level of immunity is also afforded by vaccination resulting in a vaccinoid or accelerated reaction or in an immune reaction.

TYPHOID VACCINATION

Typhoid vaccination is, of course, one of the routine immunization procedures. Stimulated by the experience with typhoid fever in the Spanish-American War, General F. F. Russell in 1908 developed an improved type of typhoid vaccine, the use of which was made compulsory in the Army in 1910. Paratyphoid A and B microorganisms were added to the vaccine during the first world war, and its use together with the improvement in methods of sanitary control practically eliminated typhoid fever. It has been estimated that if the Army typhoid rates of 1898 had obtained during World War I, there would have been a half million cases and more than 50,000 deaths from typhoid. As it was, there were less than 2,000 cases and only about 200 deaths among 4,000,000 soldiers. It is encouraging to note that since the present mobilization began in 1940, the incidence of typhoid fever has been negligible.

During the peacetime years following the first world war, the paratyphoid organisms were dropped from our vaccine and routine vaccination in the Regular Army was accomplished by a monovalent typhoid vaccine. In 1936 the Rawlings strain of *Eberthella typhosa* was discontinued and the smooth virulent Panama 58 strain was substituted. It is this strain which is currently used in the manufacture of typhoid vaccine for use in the Army. At the beginning of the present

emergency, the triple typhoid vaccine was re-adopted. This vaccine, which is manufactured at the Army Medical School, Washington, D. C., is standardized to contain in each ml. 1,000 million *Eberthella typhi* and 250 million each *Salmonella paratyphi* and *Salmonella schottmuelleri*. The initial vaccination consists of three subcutaneous injections at intervals of 7 to 10 days. The first dose is 0.5 ml. and the second and third doses are 1 ml. each. Immunity is maintained by the subcutaneous administration of 0.5 ml. of the vaccine each year. A similar dose is administered in the event of actual or potential exposure to typhoid or paratyphoid fever.

TETANUS IMMUNIZATION

The use of tetanus toxoid for active protection against tetanus is the third immunization routinely employed. The early experience in the Army with the use of this material was reviewed last year.² At that time, it was stated that since the adoption of this procedure only 4 cases of tetanus had been reported from the entire Army, and that none of these cases were in immunized individuals. It is gratifying to be able to bring the record up to date by the addition of only 5 more cases, 3 of which had received no tetanus toxoid. Of the 2 who had received toxoid, 1 had been given four injections, the last about 3 months prior to his injury, a compound fracture of the tibia. The other had received three injections, the last about 7 months prior to a gunshot wound in the abdomen. Neither of these wounds was a battle injury and neither patient received his initial treatment in a U. S. Army hospital.

In the first case, an emergency stimulating dose of toxoid was not administered, and symptoms of tetanus developed about 10 days after the injury. Response to therapy was satisfactory and the patient recovered.

In the second case, the emergency dose of toxoid was administered on the 2nd day following the injury. On this same day the first symptoms of tetanus were noted. Following this unusually short incubation period, this case terminated fatally about 12 hours after the onset of muscle spasm, despite sedation and large doses of antitoxin. It is unfortunate that an autopsy was not performed, since certain unusual features of this case suggest the possibility that a condition other than tetanus might have been the cause of the symptoms and death.

There has, then, been a total of only 9 cases of tetanus reported from the Army over a period of almost 2½ years. None have been reported following battle injury, and only 2 occurred in individuals who had completed their initial series of toxoid.

The method used for immunization is the administration of plain or fluid tetanus toxoid in a series of three subcutaneous injections of 1 ml. each at intervals of 3 weeks. Under ordinary circumstances, a single stimulating dose of 1 ml. is administered at the end of the first year after the initial series. Another 1 ml. dose is administered prior to departure for a theater of operations, unless such departure is within the 6 months' period subsequent to the administration of a previous dose. An emergency stimulating dose is administered upon the occurrence of wounds or severe burns on the battlefield, or at the time of secondary operations or manipulations of old wounds, or at any other time when danger from tetanus is considered to be a possibility.

The apparent clinical efficacy of this method of immunization would appear to corroborate laboratory evidence which has indicated that the method affords a maximum of protection.³

With the removal of certain offending peptones from the culture medium used in the manufacture of the toxoid, the

reactions of sensitivity previously reported have apparently almost ceased to occur. It is still considered, however, that in the preparation of materials of this type, the simplest medium affording the production of a potent and stable antigen should be used.

SPECIAL IMMUNIZATIONS

Those procedures referred to as special immunizations include vaccination against yellow fever, typhus, and cholera.

YELLOW FEVER VACCINATION

In view of the existence of yellow fever, particularly the endemic or jungle type of the disease, in certain areas of the world, it is fortunate that there has been made available an effective vaccine against this disease. While much can be done, time and the general situation permitting, to control and prevent the occurrence of the so-called urban type of yellow fever, the challenge presented by the jungle form is much more formidable and under some military conditions might well be impossible to meet.

The yellow fever vaccine now being used is prepared from chick embryo cultures of the 17D strain of virus.⁴ The finished vaccine is placed in ampules, then is rapidly frozen and desiccated. The ampules are then sealed and stored at freezing temperatures.

The dose is 0.5 ml. of a 1:10 dilution of the frozen and dried material. Immunization is accomplished by the administration of a single dose. Immunity is developed within 1 week to 10 days following vaccination and is considered to last for at least 4 years in adults.^{5, 6} This protection is given to personnel travelling to or through or stationed in areas where yellow fever is endemic.

While information concerning the degree and extent of exposure of United States military personnel to yellow fever

is not available at this time, it is possible to report that no cases of the disease have been reported from our troops.

The outbreak of jaundice in the Army and its relation to yellow fever vaccination has been reviewed elsewhere.⁷ Further reports of the investigations pertaining to this episode will soon be published. For the purpose of this discussion, a brief summary of certain features of this complication of yellow fever vaccination will suffice.

The increased incidence of jaundice in the Army began in March, 1942, and the peak was reached before the end of June. The outbreak had completely subsided by September, and since that time no more than the commonly expected incidence of jaundice among troops has been reported. The clinical course of the disease presented a strikingly uniform pattern in the great majority of patients. The disease resembled most closely so-called catarrhal jaundice or epidemic hepatitis of unknown etiology. The case fatality rate, based upon reported admissions to hospitals, was approximately 0.2 per cent.

Recovery usually occurred in 4 to 8 weeks and was complete in the vast majority of cases. A variety of diagnostic terms were applied to this disease. These included: jaundice without known cause, catarrhal jaundice, infectious hepatitis, epidemic hepatitis, cholangitis, obscure jaundice, yellow jaundice, and postvaccinal hepatitis. Exhaustive epidemiological and laboratory studies resulted in only negative evidence as far as demonstration of the transmissible agent of the disease is concerned. These negative results, however, have served to exclude a number of infectious diseases in which jaundice occurs. The outbreak of jaundice in the Army was not Weil's disease or any other type of leptospiral infection. It was not a bacterial in-

fection and had no relation to infectious mononucleosis. The disease was not yellow fever, nor a modified form of yellow fever. Yellow fever virus has not been recovered from any material (blood, bile, urine, liver, etc.) from jaundice patients.

Certain special features of the occurrence of jaundice among troops form the basis for the conclusion that this outbreak was a type of jaundice following the administration of certain lots of yellow fever vaccine, and that the disease was not contagious in the ordinary sense, and hence did not constitute a danger to public health.

When it appeared likely that the jaundice was associated with vaccination against yellow fever, the vaccine then in use was discontinued. On the assumption that the human serum component of certain lots of vaccine may have carried an icterogenic agent, the vaccine used since that time has been prepared without human serum, and more than a year has now elapsed since any unusual incidence of jaundice has been reported.

Further evidence that the icterogenic agent was carried by the human serum has recently been reported,⁸ and there is every reason to believe that the use of yellow fever vaccine produced without the addition of human serum has eliminated the danger of jaundice following its administration.

TYPHUS VACCINATION

Typhus vaccine is also administered to troops under certain conditions. Typhus fever, has, since ancient times, been a disease of the greatest military significance. For its control, sanitary measures are of paramount importance. These measures are, of course, directed toward the prevention of lousiness among troops. For this purpose, highly effective insecticidal agents have been developed and improved methods for the disinfection of clothing, bedding,

etc., have been adopted. In addition, typhus vaccination is required for all military personnel who may come in contact with this disease. It is believed that the vaccine now being used is the best ever developed. It is administered in three doses of 1 ml. each, with intervals of 7 to 10 days between injections. A stimulating dose of 1 ml. of vaccine is given every 4 to 6 months, or at the discretion of the responsible medical officer in the presence of danger from infection.

The conditions under which typhus vaccination has been practised in the Army have not permitted a well defined evaluation of its efficacy. Vaccinated troops have, however, operated in areas where typhus was epidemic and very few cases have developed. Of the cases that have occurred, many have been so mild as to have required special laboratory studies for their diagnosis, and the case fatality rate has been extremely low. From these observations, it is evident that typhus fever has not as yet been a problem of any magnitude. While it is too early to predict what the ultimate experience with this disease will be, it may be said with some confidence that vaccination and the other anti-typhus measures being applied afford to the troops the maximum protection available.

CHOLERA VACCINATION

The third special immunization procedure is vaccination against cholera. This disease is now largely confined to endemic and epidemic centers in Asia. In some regions of that large area, cholera continues to be a public health problem of great importance. The disease, of course, has not always been limited to that part of the world, but has on occasion been much more widespread. Epidemics were experienced in America in the last century and as late as 1911 the disease reached the port of New York. During World War I, it

occurred in Russia, Austria, Hungary, Germany, and Italy.

In certain situations cholera could become a real menace, and danger from this disease cannot be disregarded. For its prevention, chief reliance must be placed on the sanitary control of food and water. As an added safeguard, cholera vaccination is now required for all military personnel stationed in or traveling through Asia, and provisions have been made for the vaccination of troops in other areas where danger from this disease may develop.

The vaccine now being distributed for use in the Army consists of a suspension of 8,000 million killed cholera vibrios per ml. Two East Indian strains of high virulence and stability are used in the manufacture of this vaccine. It is administered in two doses at 7 to 10 day intervals. The first dose is 0.5 ml. and the second dose, 1 ml. The present policy is to administer an additional 1 ml. dose every 4 to 6 months in the presence of danger of infection.

The degree and duration of immunity established by this vaccination is still not fully determined. Experience in the Far East by the British and others indicates, however, that a sufficient degree of protection is afforded to make its use advisable.

OTHER IMMUNIZATIONS

Vaccination against plague is another procedure for which provisions have been made. Again, as in typhus and cholera, sanitary measures are stressed for the prevention of plague, and it is believed that in the majority of instances these measures will prove to be adequate protection. Plague vaccine is not now routinely administered to troops, but is supplied to forces in those areas where danger from the disease may be confronted. While there is little well controlled experience with the use of this material, it is felt that if the need arises, vaccination may prove

to be a valuable aid in the prevention of this time-honored menace.

The vaccine provided consists of a suspension of 2,000 million killed virulent plague bacilli per ml. The plan of administration is to give two initial doses approximately 1 week apart; the first dose to consist of 0.5 ml. and the second dose 1 ml. Stimulating doses may be administered at the discretion of the medical officer.

Immunization against such diseases as diphtheria and scarlet fever is not routinely practised, but materials are made available for use if the situation should require artificial protection against these diseases. The material provided for immunization against diphtheria is fluid diphtheria toxoid, to be administered in three injections of 0.5 ml., 1 ml., and 1 ml. respectively at intervals of approximately 3 weeks. Since reactions to diphtheria toxoid are not uncommon in adults, particularly those who demonstrate the combined type of reaction to the Schick test, it may be necessary to alter this scheme of administration to suit the individual case. In any event, it is felt that only those individuals who are shown by the Schick test to be susceptible to diphtheria should be immunized.

Scarlet fever streptococcus toxin is supplied for scarlet fever immunization but is administered only under special circumstances. In general, its use is confined to the protection of nurses, ward attendants, and others in close association with the disease. As with diphtheria toxoid, the reactions attending the administration of streptococcus toxin to adults require special care in its use.

PASSIVE IMMUNIZATION

The foregoing discussion has been concerned with the use of antigenic agents for the development of active immunity to certain infections. In addition, there are utilized to a con-

siderably less extent materials providing pre-formed antibodies and antitoxins for passive protection.

Tetanus antitoxin is provided in 1,500 unit doses to be used prophylactically in those rare cases in which previous conditioning by tetanus toxoid is in doubt.

A bivalent antitoxin is also available for protection against gas gangrene. This material is administered to those cases which, in the opinion of the surgeon, require its use. The prophylactic dose contains 10,000 units each of perfringens and vibron septique antitoxin.

The utilization of human immune serum and human globulin (placental extract) for the protection of individuals or groups known to have been exposed to such infections as measles or mumps is not considered practical for general application in the Army. Consequently, the use of such material has been limited largely to those instances where, for military or medical reasons, it has been absolutely imperative that all chances of infection be avoided.

NEW IMMUNIZING AGENTS

The materials and methods currently employed in the Army for specific protection from infections have been summarized. As new agents are developed and their value demonstrated, they will undoubtedly be adopted if a need for them exists. Among such materials now being studied, and concerning which the Medical Department has a keen interest, are influenza vaccine, gas gangrene toxoid, and dysentery vaccine.

Experience with the Administration of a Medical Care Program for Wives and Infants of Enlisted Men*

MARTHA M. ELIOT, M.D., F.A.P.H.A.

*Associate Chief, Children's Bureau, U. S. Department of Labor,
Washington, D. C.*

THE recent appropriation by Congress of \$18,600,000 for emergency maternity and infant care for the wives and infants of enlisted men in the fourth to seventh pay grades of the armed forces has put the program on a basis that should give assurance to the men in the forces, to their wives at home, and to those who administer the program, that there will be no interruption in this service. The discussion in Congress has made it clear that it is the present intention of Congress to provide sufficient funds to carry the program forward throughout the war.

The enthusiasm with which it has been received by the wives of the men and by the men in the Army has fully justified the effort that it has meant for administrative officers, physicians, nurses, and hospital administrators. The purpose of the program as declared by Congress is twofold: To relieve the wives of the enlisted men of worry as to how they can get the necessary maternity care for themselves and medical care for their infants regardless of their place of residence, and to reassure the enlisted men themselves that their wives and infants will have this care in their absence. The sense of security thus developed will assuredly improve

the morale both at the fighting front and on the home front.

When making the initial appropriation of \$1,200,000 for this program in March, 1943, and again when augmenting it with funds for the current fiscal year now amounting to \$23,000,000, the Congress showed its very great interest in providing all necessary medical, nursing, and hospital care for the wives of the enlisted men and for their infants. The administration of the program was entrusted to the state health agencies already responsible for the maternal and child health aspects of the Social Security Act. The appropriation act specified that state plans were to be developed and administered by the state health agencies and approved by the Chief of the Children's Bureau. Good public policy required that the administration of this program as of others involving the expenditure of public funds should be by public agencies.

There was thus placed upon the state health agencies responsibility for a medical care program that will involve, before the war is over, care of many hundred thousand mothers and children. For the first time, state and local health departments are carrying out programs of maternity and infant care that reach out into every county and municipality, that are as widespread geographically as the draft of

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

enlisted men under the Selective Training and Service Act of 1940. Fortunately, during the previous 8 months 30 state health agencies had already started programs of maternity and infant care for enlisted men's wives and children under the provisions of title V of the Social Security Act, and a small body of experience was available on which an expanded program could be built. During this period some 6 thousand wives and infants were given care and basic procedures were developed. The experience of many state health departments in the administration of the crippled children's program should not be forgotten in this connection, for from it, as from the special maternity care demonstrations started in 1939 and 1940, much of value to the present emergency program had been learned.

Once the intention of Congress to make available adequate appropriations to carry out a continuing program became clear, the development of plans has been rapid. Today all but 4 states and Puerto Rico have approved plans and are actively participating in the program. Two of these 4 states have already submitted tentative plans (Texas and Colorado), and it is expected that the remaining 2 (North Dakota and Louisiana) will send in plans soon. Further consideration is being given to coöperation by Puerto Rico. In the 6 months since Congress made the first appropriation the 47 states now coöperating reported that care has been authorized for nearly 70,000 wives and infants of enlisted men. Estimates on the basis of which the most recent appropriation of \$18,600,000 was made indicate that during the present fiscal year in the neighborhood of 300,000 wives of enlisted men may be expected to apply for maternity care. How many will apply for medical care for their infants cannot even be estimated at present.

Statistics are not yet available to show the composition of the group now applying for maternity care or their characteristics as to age, parity, race, or place of residence. Nor do we yet know about the attendants at birth, the place of birth, the mortality among mothers and infants. Plans for gathering information on these matters are, however, under way.

The responsibilities of administrative agencies in carrying out this mandate of Congress are obviously great because the medical care of many hundred thousand mothers and infants will be involved and basic principles of administrative procedure will be laid down, while at the same time due regard must be given to the efficient and proper use of large sums of taxpayers' money.

In discharging her duty in the allotment of funds to state health agencies as set forth in the act, the Secretary of Labor has issued a regulation instructing the Children's Bureau to administer the program in accordance with certain provisions of Title V, part 1, section 503(a) and (b) of the Social Security Act. These provisions relate to methods of administration, coöperation with medical, nursing, and welfare groups and organizations, reports by state agencies, and approval of state plans by the Chief of the Children's Bureau. Under this authority the Chief of the Children's Bureau has the responsibility to establish administrative and professional standards (apart from those related to practitioners performing obstetrical services) by which may be measured the adequacy and efficiency of state plans and to give information to the state agencies as to these standards so that their plans may be in reasonable conformity.

In developing the general policies established for this purpose the Children's Bureau has had the advice of the Conference of State and Territorial

Health Officers and the Maternal and Child Health Committee of the Association of State and Territorial Health Officers, and has consulted with its special obstetrical and pediatric advisory committees, and with groups of hospital administrators. The bureau will continue to seek advice from these sources. The final responsibility for establishing policies and standards rests, however, with the bureau, and when advisers differ decisions must be taken that may not always meet the recommendations of all groups. It is also the responsibility of the Children's Bureau to interpret, with the aid of its legal counsel, the intent of Congress, and to administer the program accordingly.

As state plans have been formulated and programs started, certain general administrative principles have emerged and policies have been established that I would like to discuss here. From the beginning it was clear that certain general policies had to be nation-wide or too great confusion would have resulted.

The language of the appropriation acts and the legislative history surrounding their passage have made clear the intent of Congress in passing this legislation. The most recent legislative history connected with the appropriation of \$18,620,000 for this program leaves no doubt that the Congress intended that all necessary care would be made available and that physicians, nurses, and hospitals would be paid for services. The Congress was unwilling to initiate any other plan, such as cash grants to the wife, since such a plan, it believed, would not assure the medical and hospital care and might well defeat the primary purposes of the program.

The Congress has also made it clear that this is not a so-called "charity" service, but that it is to be provided as the right of any wife of an enlisted man in the fourth, fifth, sixth, or seventh grades of the Army, Navy, Marines, or Coast Guard who applies

for care for herself or for her infant during his first year of life. No "means test" or financial investigation is involved. To permit any test or investigation that might result in uncertainty as to whether or not care would be paid for would at once nullify the primary purpose of the program and shake the confidence of the enlisted men in the safety of their wives and infants.

Another basic principle under which this program is being administered is that wives of enlisted men applying for care should have free choice in the selection of their care, provided the choice is made from among physicians, clinics, hospitals, or health agencies approved by the state health agency under conditions laid down in its state plan.

That an individual wife should be free under the program to select, if she wishes it, care by a private physician in his office, and that there should be no limitations on her choice other than those needed to assure reasonably high quality of care and economical and effective use of public funds, is reasonable and right. However, it is also reasonable and right that she should be equally free to select care in a clinic, a health center, or a hospital, either public or voluntary. She should be entitled under this program to make an arrangement for complete maternity care in the outpatient and inpatient service of an approved hospital that provides this unit of service for a fixed fee covering both medical service and hospital care.

The legislative history has made it clear that this is not a program limited to care given by private practitioners, but that all existing community facilities, including prenatal clinics, child health conferences, public health nursing services, outpatient clinics, medical social services, should be used to provide, as far as possible, complete care for mother and infant. Each of these

wives should be free to apply for and receive the services of a public health nurse without question whenever such services are available.

In approving state plans, the Children's Bureau has specified that policies may not be adopted by state health agencies that would prevent this free choice of the type of care desired by the wives of the enlisted men.

Still another general principle that obviously must be laid down for the administration of this program is that the quality of care must be kept high. A review of the discussions in Congress and in committee brings out the fact that from the beginning it has been the intent of Congress to provide as complete and as satisfactory maternity and infant care as is feasible for the enlisted men's wives and infants. Therefore, to supplement the care usually recognized as necessary for the uncomplicated maternity case or for routine medical care and health supervision of the infant, special additional care needed for complications or serious illness has been made possible under the program. This includes consultation and diagnostic assistance of specialists, prolonged hospital care, special nursing service, special diagnostic procedures as x-ray examinations, special therapeutic procedures as blood transfusions or appliances. Provision for payment for each of these special services is made in all state plans. Obviously, the quality of care will depend on the standards established by state health agencies for the selection of physicians, hospitals, and clinics offering care, and on the ancillary public health nursing and welfare services made available.

In passing the Labor Federal Security Appropriation Act for 1944, the Congress placed the responsibility for setting standards for practitioners performing obstetrical services squarely upon the state, and withdrew from the Children's Bureau its former right to

establish these standards. State health agencies can no longer rely upon the federal agency in this respect, but must look to their own statutory authority to maintain high standards of obstetric care. For all other standards of professional service the Children's Bureau still has the power to set up the measuring sticks it will use in approving state plans. I would caution the state health agencies to look sharply at the standards of obstetric care they are setting and take all necessary steps to keep them at a high level so that we may maintain the excellent record in the reduction of maternal mortality of the past decade.

The last and perhaps the most obviously controversial principle that I want to discuss here is that payment for care under this program by the state health agencies whether to physician, hospital, clinic, or nurse must necessarily be at fixed rates based on average costs of adequate care excluding luxury services.

Experience has shown that in the case of hospitals and clinics, such rates may be reached comparatively easily on the basis of the so-called "ward-cost-per-patient-day." Such a basis of computation of cost of hospital care was established and is now in use under the Crippled Children's Program; it covers the cost of interne and other paid physicians' services as well as all other costs of routine care. This does not mean, however, that accommodations would necessarily be in wards though wards may be used, but that the rate paid would be based on ward costs. Actually the rate paid in most hospitals exceeds the rate scheduled by the hospital as the charge to ward patients; it may even reach or nearly reach the semi-private rate. The hospital may place the wives of servicemen in any accommodations they wish to make available, but the hospital cannot expect a higher rate of pay

than the ward-cot-per-patient-day.

In developing rates for payments to private physicians, on the other hand, the task is not so easy. Maternity care is a unit of service that lends itself very satisfactorily to a fixed fee plan. In arriving at a fixed fee, therefore, it becomes necessary to establish rates which represent a fair average of the usual range under the sliding scale, excluding the maximum charges made to patients in the highest income brackets and bearing in mind all the while that there will be no unpaid bills if required reports are submitted. Because of the wide variation in maximum fees charged by private practitioners in different parts of the country, it has become necessary for the federal agency to set a maximum.

A corollary of this principle of fixed rates for medical and hospital care to be paid by state health agencies under this program is that additional fees will not be charged by private physicians, and hospitals will not charge the recipients of care extra when accommodations other than ward care are made available. To permit such additional charges would force the wives of the enlisted men into negotiating with physicians or hospitals in respect to the fees or rates they would be willing to pay over and above the amount paid by the state health agency. If such negotiation with physician or hospital were permitted it would be, in effect, a means test applied by the physician or hospital which would defeat the primary purpose of the program, namely, the provision of care without cost to the wife of the enlisted man. It would at once introduce an element of uncertainty as to whether the care is assured.

The question has been repeatedly raised as to whether it would not be acceptable for a state health agency to pay the cost of hospital care and allow the wife of the enlisted man to nego-

tiate the medical fee privately with her physician. If a wife of an enlisted man is financially able to pay higher fees charged by some obstetricians and chooses to do so, it has to be assumed that she can and should also pay for hospital care. Any other arrangement would mean that pressure could be brought to bear on any enlisted man's wife to pay physician's fees that are in excess of those paid by the state health agency and to apply to the state health agency for hospital care only.

To make it possible, however, that wives of enlisted men who wish to do so may make payments toward the total cost of their care provided under the state plan, state health agencies may arrange to receive voluntary contributions toward the total cost of their care from the recipients of care or from others in their behalf. The money so paid would be added to the funds for the program in the state treasury, and would not be used to raise the physician's fee or the payments to hospitals.

I have discussed at some length these basic policies underlying the administration of this maternity and infant care program because many individuals have not understood the reasoning back of these decisions. The rapid development of the program has brought many difficulties, especially those involving the location of personnel to handle the detail of office administration. I am glad to be able to report that order is taking the place of confusion; procedures have been clarified; and policies are better understood.

The speed with which small divisions of maternal and child health have grappled with the job and the efficient methods that are now being established are a great credit to the directors and their staffs and to the others in the health departments that have given the maternal and child health divisions a hand. It has not been generally appreciated, and this applies also to the

Congress, that most of the Social Security Title V funds are spent by the states for local service and that only relatively small central state administrative staffs were available to take over the large task of the emergency maternity and infant care program. It is a great credit to the states that it has been put into operation as promptly as it has.

Of course, many difficulties are yet to be overcome, but I am sure the way will be found, if together we continue to discuss the pros and cons and keep in mind the welfare of the people we are trying to serve as the test of the

reasonableness of our decisions. Is it unreasonable to ask that we strive to give as good care to the wives and children of men in the armed forces as the Army and Navy are giving to the men themselves, and that we give it as freely and certainly? With such a goal in mind most difficulties can be smoothed away. No program of this size and importance could be developed without many growing pains and without some mistakes being made. The experience to be gained is very great and will stand us all in good stead as the maternal and child health programs expand in the years to come.

Epidemiological Notes on Meningococcal Meningitis in the Army*

CAPTAIN PHILIP E. SARTWELL, M.C., A.U.S., F.A.P.H.A., AND
CAPTAIN W. MYERS SMITH, M.C., A.U.S., F.A.P.H.A.

*Division of Preventive Medicine, Office of the Surgeon General,
Washington, D. C.*

THE Army's health record has been remarkably good during the present war. In only a few respects has it been less favorable than that of the small peacetime army quartered in permanent installations and made up largely of seasoned troops. Meningitis is the chief disease which has increased in prevalence, and for this reason it is believed that a review of our experiences to date with meningococcus infections should be worth while.

It is emphasized that this paper is not intended as a complete epidemiological study, but merely as a presentation of some of the outstanding points about the incidence of the disease during the past winter and spring in Army camps and stations in this country. No reference is made to carrier rates, types of meningococci found, or other bacteriological features because these are fully discussed in other papers presented at this meeting.

Some comment should be made as to the reliability of the data on Army incidence. This is undoubtedly more complete than civilian reporting, but cannot be regarded as entirely accurate. Individual judgment and difference in diagnostic criteria give rise to differences in reporting. The reporting of menin-

gitis cases in which the etiological agent had not been bacteriologically identified varied at different posts; such cases were often classified as "meningitis, other types," and were not always included in incidence rates. There were also numerous cases of septicemia, presumably meningococcal, where positive cultures were never obtained and no report was made. Furthermore, the data used were weekly morbidity reports which are provisional and subject to later correction.

It is known that meningitis occurs in cycles lasting several years with a sharp seasonal rise and fall superimposed on the long cyclic wave. The years of highest prevalence in this country since the first World War were 1929 and 1936. The incidence is also high during wars and among military forces. The present war has coincided with an expected cyclic increase and it is likely that the resultant of these combined factors has been a much higher prevalence than would have been produced by either one acting independently.

The last major epidemic of meningitis in the United States Army was in the winter following our entry into the first World War. It was an explosive outbreak reaching its peak in January, 1918, and subsiding by the following August nearly to the previous level. A secondary peak followed in September,

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

FIGURE 1

RATE PER 1000 PER ANNUM, BY MONTHS
-----1917-19 + ————1942-43

but the rate was less than one-third of that attained in January ¹ (see Table 1 and Figure 1).
By comparison the curve of the recent epidemic is strikingly similar. It, too,

began within a year after our entry into the war, although somewhat longer after the beginning of mobilization. The peak incidence was two-thirds of that in 1918 and occurred in the month of March; but the increased rate has lasted longer so that the annual rate, when computed at the end of the year 1943, may well be nearly as high as that for 1918.

Coincidentally with the outbreak of meningitis in the Army, there occurred a greatly increased prevalence in the civilian population (see Table 2). Both increases, the military and the civilian, were, roughly, tenfold above the normal prevalence. In keeping with the well known predilection of meningitis for military forces, its incidence in the Army both in peacetime and during the

During the epidemic there was a distinctly higher prevalence of meningitis in the civilian population along the Atlantic and Pacific seaboards than in the interior of the country. Arranging the geographic regions in

the order of ascending meningitis incidence for the first half of 1943, we have the following sequence: The West North Central States were lowest, followed by the West South Central, East South Central, Mountain, Middle Atlantic, South Atlantic, Pacific, and New England states, which had the highest incidence. The map, Figure 2, illustrates this point.

In the Army, on the other hand, no distinct geographic localization was observed. The epidemic began at approximately the same time in all portions of the country although there was a variation of several months between its onset in individual stations. Figure 3 is a map of the United States, divided by service commands, on which the incidence of meningitis in the Army over the same 4 month period is shown for comparison with Figure 2.

Table 3 shows the course of the outbreak in terms of annual rates by weeks from October, 1942, through August, 1943. This is a composite picture made up of much briefer individual

FIGURE 2

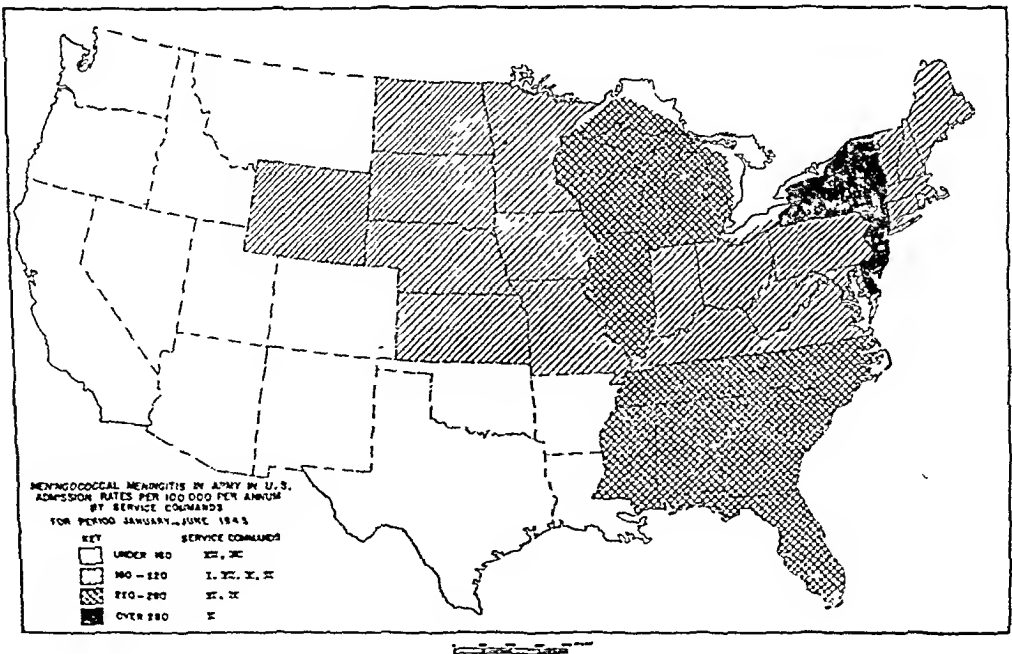

outbreaks at separate posts. The peak was reached in the week ending March 27. It will be noted that while the descending portion of the curve is quite similar to the ascending portion, the incidence in August, 1943, was still roughly three times as high as in the previous fall. On the basis of past experience with civilian outbreaks, it is anticipated that the incidence will continue to be above the normal inter-epidemic level during the coming year. There are, however, reasons to believe that it will not be as high as during the past winter. These are the smaller proportion of new recruits who will be in training and the likelihood that spacing of troops will be more ample than was possible last winter.

Through the courtesy of Dr. John J. Phair, Director of the Army's Meningitis Commission, a preliminary tabulation has been made of the frequency of meningitis in relation to duration of military service. This is based on a total of 1,337 cases that occurred in the early part of the epidemic in all

parts of the country. This relationship is shown in Table 4, and graphically in Figure 4. Of the total cases, 57 per

FIGURE 3

cent occurred in the first 3 months after induction and 29 per cent occurred in the period between 30 and 60 days after induction. Only rarely did men who had been in the Army more than a year develop meningitis. While it is true that these figures must be interpreted with some caution because they do not take into consideration the population at risk in each group, nevertheless they do portray the decided affinity for new recruits. The number of men inducted each month during the year preceding collection of these figures was fairly constant, so it may be assumed that the population by length of service in months up to 1 year was reasonably uniform.

TABLE 4

Meningococcal Infections by Duration of Army Service in Months

by Weeks at
Army Posts

During the 4 month period, January through April, 1943, the incidence in terms of cases per 1,000 strength per annum was as follows: For all stations with a strength above 20,000 it was 3.2; for those in the range from 10 to 20,000 it was 2.8; and for those of less than 10,000 it was 1.0. This marked difference is believed to be related to the greater proportion of new recruits and more rapid turnover at large stations.

There has frequently been speculation as to the possible association of meningitis and respiratory disease. Both diseases tend to reach their seasonal peaks in late winter or early spring. It has been suggested that increases in upper respiratory disease tend to facilitate the transmission of meningococci from person to person. The association between meningitis rates and the rates for common respiratory diseases (including influenza) was studied in stations above 20,000 strength during the 4 month period from January through April. Ports of embarkation, general hospitals, maneuver areas, and urban centers consolidating several units were omitted from this study. A fourfold association table was constructed dividing the stations into those having rates above and below the mean for meningitis and for common respiratory disease. A statistically significant positive association between the two variables was found. It was noted that in several stations secondary increases in meningitis followed secondary rises in the incidence of common respiratory diseases. The meningitis peak tended to follow the respiratory peak after a variable period, often 4 to 6 weeks.

Weekly incidence rates at certain posts are presented in Figure 5. These posts were chosen as showing interesting features. They each had a strength of 20,000 or over. Posts A and B are of interest because they are situated less than one hundred miles apart. Post

A had a decidedly low rate, without anything that could be called an epidemic during the entire 11 month period of study, from October, 1942, to August, 1943. Its maximum rate in any week was 5 per 1,000 per annum, and its average rate for the period from January to April was 0.8. This post is a recruit reception center where men remain usually less than a week after induction and are then shipped to other stations for training. It is a permanent installation with excellent housing facilities in either brick or well constructed frame barracks. Double decking of bunks is rarely necessary during the winter. The weather at this post was unusually severe. There was a moderate but sustained incidence of respiratory disease lasting from January to April.

Post B nearby is about twice the size of A. It is a replacement training center. Due to military necessity the housing of troops was crowded, with 90 to 100 men in barracks built for 63 men. This situation existed until May but has since been corrected. Common respiratory diseases at this camp reached a fairly high peak in January but declined the next month. A lower secondary peak occurred in April. Meningitis reached a peak in early March, with a less marked secondary increase in June. The pronounced lowering of the incidence in April is probably related to the administration of sulfonamides to a part of the force.

Post C is an Army Air Force basic training center on the middle Atlantic coast. New recruits arrive direct from reception centers and remain for 4 weeks of intensive training. The monthly turnover of troops during the winter was more than 10,000; in fact, during January 27,000 men were received. These troops were quartered in hotels, and it was temporarily impossible to provide the minimum amount of floor space in sleeping quarters which

is generally considered desirable in stations housing new recruits. In June the strength of the force was much reduced and a minimum of 50 square feet provided. Respiratory disease incidence was quite high for a period of 4 months. Meningitis reached a sharp peak in late February and gradually declined with a secondary peak in late May.

Post D is a very large permanent station in the Southeast. Its housing facilities consist of hutments and wooden barracks and are considered good, but some overcrowding was present at times. Two infantry divisions were in training here during the winter. Respiratory disease reached a rather high peak in January followed in 2 weeks by a sharp elevation of meningitis rates. The incidence of meningitis then dropped to a moderate level which persisted until May. Prophylactic sulfadiazine was given to a small part of the force in April.

Post E is another air force station in the South where the strength increased greatly during the winter, necessitating crowding of troops. During the 3rd week in March there was a sharp meningitis peak, with another 4 weeks later. The common respiratory diseases reached a peak incidence during January, February, and March, and declined sharply during April.

Post F is a newly built camp which was still under construction at the beginning of the season. In January and February an infantry division was activated, increasing the strength very rapidly from a few thousand to many thousand men. There was no serious overcrowding, however. This division was made up chiefly of young men direct from civilian life. Practically from their arrival there was an extremely high prevalence of respiratory disease which fell to normal levels in April. Meningitis rose abruptly and

attained a rate of 37 in the last week of March, after which it dropped even more abruptly to rates of less than 5. Sulfadiazine was administered to half the division at the height of the epidemic, undoubtedly influencing the subsequent picture.

Post G had an experience quite similar to several already described. Practically no cases occurred outside the period from January to May. This is a southern infantry replacement training center which receives men from recruit reception centers and gives them several months of basic training.

Post H is a southern station in the same state as posts E and F. Two infantry divisions were trained here and field maneuvers were held during the winter. The point to note here is the fairly constant level of incidence of meningitis from January to June, without any marked fluctuation.

Post I is located in a middle western state. It is a large Army air force basic training center. Upper respiratory disease, atypical pneumonia, and meningitis have been more or less constant problems at this post for some time. Meningitis increased steadily to a peak of 42.2 per 1,000 per annum in early April; this is the highest rate attained by any of these eleven stations. It then dropped abruptly to an endemic level of 2 to 3 per 1,000. The respiratory rate was moderately high from December through March, with a peak in February. Several of the same factors have been operative here as at post C; namely, overcrowding and the reception of large numbers of new troops who remain long enough for susceptibles to come down with these diseases and then are replaced by new groups.

Post J is in a midwestern state and its troops are garrisoned principally in permanent buildings. The buildings are scattered over a wide area and there has been no overcrowding. It is a field artillery school and its personnel on the

average consist of distinctly more seasoned troops than make up most of the other stations discussed. It had the lowest incidence by far of both meningitis and respiratory diseases of the eleven stations, the highest meningitis rate being 4.7 and the average for the period January through April being 0.4.

Post K is in the Pacific Northwest. Two infantry divisions were located here, one of them activated in December. Overcrowding was a definite feature of this camp during the winter. In December, immediately after activation of the division, there occurred an explosive but short-lived respiratory outbreak which produced an incidence nearly twice as high as at any of the other eleven stations. Meningitis appeared in January, reaching its peak in the middle of the month, and then dropped off moderately. At the end of the month sulfadiazine was given to almost the entire force and meningitis practically disappeared. This was the first large-scale use of the drug for such a purpose. Only sporadic cases have since occurred.

The last graph depicts the rate by weeks for the entire Army in this country. It is clear from this that most of the stations discussed had rates far above those for the country.

Among the comments made by medical inspectors at posts where meningitis occurred, none was more frequent than the statement that there was generally no direct relationship between cases. Seldom could a contact even of a casual nature be shown with a previous case when a new case developed. The control measures employed varied to some degree but included daily medical inspections of contacts for at least 7 days. In some posts partial segregation (working quarantine) of contacts was practised but this is not considered an effective measure. Suspects and cases were promptly hospitalized. Measures were adopted to reduce overcrowding

both in barracks and at gathering places. Other measures specifically aimed at safeguarding sleeping troops against transmission of respiratory organisms were employed; such as head to foot sleeping, "cubicization" by means of shelter halves, and the insurance of proper ventilation.

Sulfonamides were administered to large numbers of troops in several of these stations with apparently striking effects in reducing the incidence. This is unquestionably a most important development in meningitis control, but its consideration is beyond the scope of this paper. A circular letter has now been issued by the Surgeon General outlining the indications for this procedure.

We have no evidence that the cases encountered in this epidemic were any less severe than in other outbreaks. However, sulfonamide therapy has been extraordinarily effective and the case fatality rate has been below 5 per cent or, roughly, one-tenth as high as during the 1918 epidemic. In a large number of cases the diagnosis was meningococcemia and invasion of the central nervous system did not occur, due presumably to the prompt administration of sulfonamides.

SUMMARY

1. Review of the Army incidence of meningococcal meningitis during the past year is presented.

2. The incidence has been somewhat lower than in 1918, but the outbreak has been comparable in various ways to that in the first World War.

3. The incidence in the civilian population increased in the same proportion as in the Army.

4. The geographical distribution in the Army was fairly uniform in all regions of the country in contradistinction to the concentration of civilian cases in the eastern and western seaboard states.

5. Data are presented which indicate that a majority of all cases occurred in recruits who had been in the Army less than 3 months, and that the highest incidence was between

30 and 60 days after entry into the service.

6. The definite relationship between size of post and meningitis incidence is shown.

7. The possible relationship between respiratory disease prevalence and meningitis incidence is explored and evidence of association obtained.

8. Rates of incidence by weeks in various posts are presented. Factors influencing the rate are discussed. The principal factor appears to be the presence of a high proportion

of unseasoned troops, especially when there is a rapid turnover of such troops.

9. Control measures are discussed. The outlook both for treatment and prevention of meningococcal infections has been radically improved by the sulfonamides.

Progress in Establishment of Standards on Allowable Concentrations of Toxic Dusts and Gases

At a recent meeting of the committee of the American Standards Association concerned with approval of Allowable Concentrations of Toxic Dusts and Gases, it was reported that 6 standards had been approved during the present calendar year, and that altogether 12 standards had been promulgated under the auspices of the committee since its reorganization two years ago. Senior Sanitary Engineer J. J. Bloomfield of the National Institute of Health represented the American Public Health Association.

The standards now being considered are on methanol, styrene monomer, formaldehyde, trichloroethylene, and acrylonitrile. A standard on toluene has been approved and published. The proposed standards for oxides of nitrogen approved by the committee are now being processed through the Safety Code Correlating Committee.

Considerable discussion was given to the preparation of a standard for silica dust exposure. It was finally decided to prepare a standard which would take into consideration the data now available for threshold limits for various industrial dusts with a silica content. The consensus of opinion was that no single maximum allowable concentration could be developed in view of the fact that no two dusts containing silica have the same effect on health, even when the silica content may be the same.

The chairman was authorized to appoint subcommittees to consider the following standards: methyl chloride, which is now being used in place of Freon as a refrigerant; hydrofluoric acid, fluorine and fluorides; and a standard for exposures in luminous painting to take care of radon, gamma rays, and radium dust.

Objectives in the Programming of Post-war Sanitation Works*

EARNEST BOYCE, F.A.P.H.A.

*Senior Sanitary Engineer (R), U. S. Public Health Service,
Federal Security Agency, Washington, D. C.*

WE are now engaged in a great war that is testing our capacity to produce, to arm, and to conquer. Because of the success of their planning, we may never know how much we owe to military staff groups who through the years of peace have prepared the blueprints of war. But when military objectives are won, plans will be needed to guide us upon our return to a peacetime economy. We can lose the peace on the home front through a lack of preparedness.

Our battles are being won because military men with a vision stayed with their planning despite the popular belief that war would be no more. It was not easy for them to go counter to the wishful thinking of a nation that wanted peace—and it will not be easy now to gain popular support for the staff work that must be done in the preparation for peace. Unlike the plans for war, the plans for peace must be of, for, and by the people, and acceptable to the majority. It is proper that we should be concerned with the problems of the post-war period and attempt to analyze the conditions that may give rise to emergency situations, and to find in advance solutions for them.

There are those who have questioned the ability of a democracy to meet emergency problems without resorting

to the direct action procedure of the dictator. The fallacy of their reasoning lies in their failure to recognize our freedom to anticipate emergencies—and by planning their solution in advance to remove the emergency character of their occurrences. We are not regimented when we plan together for our mutual good.

One of the fundamental principles that give strength to our democracy is the recognition it gives to the freedom of the individual citizen to join with his fellows in the formulation of such governmental policies as may be acceptable to the majority of the group.

The problems of post-war reorganization will retain their emergency character only to the extent that we fail now to anticipate them. This nation can ill afford the social and economic loss that must come if we leave to emergency salvage measures plans for the proper utilization of the most valuable of all our nation's resources—its man power.

Past experience has indicated the value of a public works construction program as a means of providing employment during a period of economic depression. It is therefore logical that our plans for the future should have incorporated in them proposals for the use of this method of employment stabilization. It is easy to classify long lists of needed public works and to envision the material changes that can be brought about by their construction.

* Pre-ented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

It is not so easy to appreciate that material change alone will not make this nation strong or its people happy. There is a need in the planning of our post-war procedures to go deeper than the mere providing of bread alone. We need to recognize that, unless in our planning we keep alive the essentials of true democracy, in spirit our nation can starve in the midst of material plenty. Certain basic principles are essential to the continued vigor of our democracy, and in our planning for the post-war period it is important that we recognize these principles and thus establish better the very foundation of our government.

There are many would-be Aladdins who long for a magic lamp to conjure up the objects of their wishful thinking and who envision a post-war world, limited by their conception of what that world should be. Unconfessed dictators at heart, they would impose their particular pattern of perfection by fiat act. Material progress can, and in emergency sometimes must, be made in this way, but the principle is foreign to the spirit of the cause for which we fight.

Any progress that is made without full recognition of the essential need for an informed and responsible electorate will be based on the shifting sands of political expediency without adding to the stability of a free government of the people. Freedom of action is equally essential to the spiritual growth of an individual and to the civic development of a town or city. This freedom is also essential to the vitality of our democracy. Mistakes must be eliminated, not by removing the freedom of individual or group action but rather by the slower process of educating the majority. Real governmental leadership will have been achieved when, through the advantage of careful, economic, social, and engineering analysis, factual information will

make it possible for an informed electorate to assume its proper civic responsibility.

Because of national emergencies, first economic and then military, it has been necessary to expedite construction programs through administrative procedures that have emphasized the speedy attainment of essential national objectives. The immediate success of these procedures in meeting emergency situations makes an appeal to those who are thus relieved of local responsibility.

Should emergency measures that do not require a mature civic response on the part of the majority become permanent, it is inevitable that there will be a loss of civic interest that can lead to an eventual loss of civic liberty. As citizens of a democracy, we must respond to the trust that this form of government places with us and face civic responsibility free of the immaturity of wishful thinking—or we will not be worthy of or long retain the freedom that we now enjoy.

The development of a program of post-war public works will have missed an essential objective if there is a failure between the planning and construction stages to develop a local interest in and civic responsibility for the proposed improvements.

The encouragement of local civic interest in public affairs, including public works, is so essential that the development of governmental procedures which will not only promote but will require this interest may well be a basic objective in programming post-war sanitation works. This will require an integration of the functions of local, state, and federal governments in the planning and development of public works in order to accomplish the program without a usurpation of responsibilities that should remain with local government, on one hand, and an uncoördinated effort that would fail to provide a maximum national benefit, on the other.

A second major objective in the programming of post-war sanitation works may well be the development of procedures that will encourage the planning of projects sufficiently ahead of the construction period and in such detail as to permit a thorough understanding of the objectives to be attained. The development of a proper civic interest in proposed public works requires that there be a time interval between the design and the construction stage of a project to permit an educational presentation to the public of the need for the project.

There should be a more general public appreciation and acceptance of the value of basic engineering data in the design of public works and of the time required for the development of the proper design. Back of every properly designed engineering project there must be a well defined objective—it is the vision of that objective that gives incentive to the engineer to translate it into reality. The need for public works is evident to the engineer responsible for the maintenance of a service facility long before there is a public consciousness of this need. The public tacitly pays homage to the engineering planning back of the completed structure by the ready acceptance of its usefulness. Unfortunately, the same public frequently forgets that the design must be based on a careful engineering analysis of factual data if the completed structure is to be the most effective and economical solution of a public need.

As we study tomorrow's problems, we recall the unemployment emergency of a few years back—and the popular demand for the immediate starting of public construction work. We should not forget that this emergency need for employment found us unprepared for the effective utilization of the manpower then available—and how the public works official was expected to do

the impossible—to provide worth while construction projects without the guidance of adequate planning.

Credit is due to those who faced that emergency and through whose efforts much was accomplished. That was an emergency period and our failure to be ready to undertake the responsibilities that came with it was understandable if not excusable. To have failed to learn by that experience is neither.

We are prone to envision programs of post-war public works against the background of a program that was designed to meet an emergency situation. If our future public works programs are to be most effective in stabilizing a national reëmployment situation, certain controls may be necessary to insure the scheduling of construction work at such levels of activity as may be necessary to avoid either a wasteful surplus or a shortage of the necessary supplies and labor.

The post-war public works program will have failed in a proper objective if it functions only after an anticipated situation has been allowed to become an emergency.

We can face the complexity of these post-war problems and attempt to reach rational solutions—or we may become lost in the confusion of conflicting interests and forget that the freedom we enjoy can be had only through the acceptance by the majority of necessary rules of orderly procedure.

We may wait until dole-like contributions of federal funds are necessary to stimulate a sick domestic economy—or we may in government, as in public health, recognize that prevention is better than a cure, and provide the funds necessary for advance planning.

A post-war public works program will be of value in the stabilization of employment to the extent that there is at all times an adequate reserve of planned projects ready for construction, and a

public willingness to schedule their construction to meet this need.

A reserve of planned public works projects will require more than the mere tabulation of recognized public needs. Advance planning will require the completion of detailed engineering studies and the preparation of engineering reports. It will require that there be an acceptance of the project by the sponsoring community and the completion of necessary legal and financial clearances for construction. The orderly development of a reserve of planned public works may well require that there be a coördination of governmental interest, local, state, and federal, in the planning of projects for deferred construction. The maintenance of an adequate reserve of planned public works to attain a national objective of

effective employment stabilization may require that there be an acceptance of some control of possible over-expansion of construction activity.

Through a properly integrated program of public works, this nation can achieve a standard of national well-being beyond our present expectations. There is little need to catalogue the improvements that can be made in the field of sanitation—they are known to most of us.

If we truly believe in a democracy and are willing to work at keeping its principles alive, we can have this material progress and at the same time save the spirit that has made this nation great. If in the planning for the future we neglect democratic procedures, our public works may well become but a monument to a decadent civilization.

The Battle for Health*

A Radio Script

IRVE TUNICK

*Radio Adviser to the New York Local Committee for the Association's
72nd Annual Meeting*

(*Music.....Organ fanfare...*)

Announcer: The Columbia Broadcasting System, in coöperation with the American Public Health Association, presents: The Battle for Health!

(*Music.....Strong chord, fading out as.....*)

Announcer: This week, in New York City, public health officials from almost every republic of the Americas and representatives of the United Nations, are meeting for the Wartime Public Health Conference... For them — and for all Americans — the Columbia Broadcasting System presents this program on The Battle for Health. Later in the program you will hear Surgeon-General Thomas Parran of the United States Public Health Service introduce Brig. General James S. Simmons, this year's recipient of the Sedgwick Memorial Medal for "Outstanding Achievement in Public Health."

(*Music.....Fanfare.....*)

Narrator: We are going to paint three pictures — two portraits and a mural. Together they will form a sketch — a panorama of the Battle for Health. Many names and events brilliant in the history of public health will not be mentioned — but their value is inherent in the story we tell. The Battle for

Health has not been a series of isolated skirmishes. It has been — is today — an all-out, all-encompassing war against the greatest enemy of man — disease!

(*Music.....Chord...*)

Narrator: I wonder if you have ever heard of Lemuel Shattuck? He was a Boston citizen — born in 1793, died in 1859. In those days, as in our own, men were quick to apply the epithet —

Haggard: (In fast) Radical! Agitator!

Shattuck: That will be enough of that, Mr. Haggard!

Haggard: You deny it, Mr. Shattuck?

Shattuck: Deny what?

Haggard: That you are appearing before this legislative committee with no other thought in mind than to arouse the people of Massachusetts into a frenzy of fear? Why? So that the medical profession can grow rich on the fruits of fear! You keep shouting "Disease!" "Plague!" "Death!" And the people shudder and shake and come running for potions!

Shattuck: That's a vile thing to say.

Haggard: Is it, now?

Shattuck: What I propose would cut

* Broadcast over the Columbia Broadcasting System in connection with the Association's 72nd Annual Meeting in New York, N. Y., October 14, 1943. This program was arranged through the coöperation of Leon Levine, Assistant Director for Education, Columbia Broadcasting System, New York, N. Y., and directed by Richard Sanville.

down the income of every physician in the state. It would make our people healthy.

Haggard: So — — — now you are a philanthropist!

Shattuck: I am merely a man seeking to better the lot of the people of this country. I don't know why you — — — and the other politicians — — — are so against my proposal!

Haggard: Then permit me to enlighten you, Mr. Shattuck. We consider your proposals unnecessary, unGodly — — — and unconstitutional!

Sound: Applause and murmur of Approbation

Shattuck: I don't understand why. This proposal is the result of an intensive study of the health conditions of Boston made at the suggestion of some of our leading citizens as well as those of the medical profession. Our report speaks for itself. Conditions in this city are abominable. It is a disease-trap — — — a plague-center — — —

Haggard: (Interfering) I will not hear the good name of our city of Boston so defamed!

Shattuck: Defamed? Good Lord! Since when are facts libelous? Listen to me — — — don't interrupt! I want you to understand every word of what I say...I won't annoy you with statistics — — — nor with descriptions of what we saw — — — I don't think your fat stomachs are strong enough to take it. But I will give you some choice warnings...Listen to them — — — unless we take immediate action — — — prompt, efficient, all-embracing — — — the population of Boston — — — the whole state for that matter — — — is facing the greatest catastrophe in the history of our nation. Smallpox, malaria, cholera, yellow fever, consumption. and a

dozen other deadly diseases are ripening right now in the overcrowded, unsanitary slums of Boston. You talk of the good name of Boston! Rot! You're no more interested in Boston than I am in Siam! You represent intrenched, vested power! You fear a progressive, healthy, alert-minded populace! That is why you are against this bill to set up in the city of Boston a board charged with the responsibility of supervising the public health.. Deny that — — —

Haggard: I do deny it!

Shattuck: Then why do you fight this proposal?

Haggard: I fight it on the Holy ground that God proposes and God disposes. If it is His will that plagues and disease kill the sinners — — — then they must die! I fight your proposition on the ground that it is unconstitutional — — — nothing in our basic law provides for the setting up of such an agency as you suggest. That is my stand!

Shattuck: You dare to call on His name to back your perfidy! Why did God, then, permit Jenner to discover the secret of vaccination? If it was His will to destroy, why did he let the genius of man discover a way to circumvent His anger? Why? Is it blasphemy to save the poor and sick?

Haggard: I — — — I did not mean that.

Shattuck: You say it is unconstitutional. I say it is basic democracy — — — and therefore the very essence of our Constitution! The agency we would set up would be empowered to abate sanitary nuisances — — — check up and report on the appearance of contagious diseases in our community — — — vaccinate against the

smallpox — — control the distribution and the use of patent medicines! Why — — this would be the people's health insurance — — paid for by them, controlled by them, dedicated to their own betterment. As for the Constitution — — there is a phrase in it concerning the Pursuit of Happiness, I believe — —

Haggard: Yes — —

Shattuck: There is no happiness for the sick and the afflicted. There is no freedom for the child chained to slums and fever — — nor for his parents — — weak and crippled by disease. That is my answer to your objections —

Voice: (Off mike) Wait! I want to speak —

Haggard: Who are you?

Voice: (Coming on mike) Just a plain man of Boston. From the Fourth Ward... Your Ward, Mike Haggard. Man, there is only this to say... We want to be protected against disease. This man says the way to do it is by setting up a health agency. You do it, Mike Haggard — — you hear me — — — you do it! We people want it — — — and we'll get it! You do it, Mike Haggard — or just as sure as the sun comes up over the Cape, you'll be patching your pants come next election!

Haggard: My dear constituent, I — — —

Voice: I'm going back to the neighborhood, Mike — — and tell the folks what I've heard! Will I tell them you will deny us the right to live? Eh, Mike Haggard?

Haggard: No — — No, of course.

Voice: You will vote for this bill?

Haggard: I — —

Voice: Speak up, man — — how will you vote?

Haggard: I — — I will vote for the bill!

(*Music:* Tag, full, up and under...)

Narrator: That is the first portrait — — Lemuel Shattuck — — crusader, pioneer, fighter for health. Lemuel Shattuck sparked the flame of democracy in the hearts of the people — — and the people acted. The health department he fought for was established — — the first such health organization on this continent. Perhaps it was Shattuck who first inspired Stephen Smith. That was in New York — — the year — — 1864. Stephen Smith — — a young physician battling for the health of the million crushed within the limits of the City of New York. A typhus epidemic was sweeping the city, and Smith was put in charge of the hospital tents pitched on Blackwell's Island. He soon was an old hand at filling out death forms — —

Smith: What is the name of deceased, Billy?

Billy: Er — — let's see — — kind of hard to make out on this tag. O — — O'Donnell, I guess it is. That's it — — O'Donnell — — Molly O'Donnell.

Smith: Address?

Billy: Address now — — Ah — — er — — East 22nd Street!

Smith: Another!

Billy: Eh?

Smith: That's the eighth death this week from that same block!

Billy: No wonder. I know the place, I do. A little patch of brimstone in a furnace o' Hell!

Smith: Bill — — will you take me there?

Billy: You?

Smith: Yes.

Billy: And why would you want to be going to such a dive?

Smith: I want to see how the people live.

Billy: The answer is that they don't live like people, Dr. Smith — — 'tis more like cattle — — and starved cattle, at that.

Smith: Immigrants?

Billy: Aye.

Smith: Come on, Billy — — I want to see the place.

Billy: Right you are. Only plug up your nose and belt in your stomach — — 'tis not the Garden of Eden you're visiting!

(Music: . . . Tag in and out . . .)

Sound: Off mike voices — — squeals of kids running about

Billy: Whew — — and hold your nose, Dr. Smith!

Smith: (Gasping) Lord — — what a stench — —

Billy: 'Tis a well-mannered word you use.

Smith: What holds this place together?

Billy: The smell. It cements the rotten walls.

Smith: How many people do you figure live here, Billy?

Billy: None that live. About six to a room that exist.

Woman: (Coming up — — Irish) And what would you be wanting?

Smith: I'm Dr. Stephen Smith — —

Woman: Get out!

Smith: But — —

Woman: (Calls) Pete!

Smith: Now, madam, I am only — —

Pete: (Coming up) What is it?

Woman: This one has come to see the sights.

Pete: So? Pretty — — what?

Smith: I'm a doctor. I've come because — —

Pete: Because what?

Smith: Because there have been eight deaths from typhus registered from this address this past week.

Pete: Eight? Man, you're way off. Eighteen, maybe. We don't count.

Smith: Why do you stay here?

Pete: And where might we be moving to? The Astor mansion?

Smith: There are other tenements?

Pete: Aye — — with rent to pay.

Smith: You don't pay rent here?

Pete: We come and go as we please.

Smith: Who owns the property?

Pete: The devil himself.

Woman: Make him get out, Pete. We don't want him here.

Pete: Aye. Out with you — —

Smith: But — —

Pete: Out! Don't you have no respect for the dying? We're dying — — let us alone to die in peace!

(Music: . . . Tag in and out . . .)

Bryant: I know the state of the slums in this city, Dr. Smith — — but what do you expect me to do. I am a newspaper publisher — — —

Smith: Mr. Bryant, I've found out who owns the property. It wasn't easy — — because he kept his name fairly well hidden. But now I know it — —

Bryant: Who is it?

Smith: Never mind the name — just believe me when I tell you that he is one of the biggest men of the city. I have spoken to him. He refuses to renovate the place and make it habitable. There's only one way to make him act — —

Bryant: How?

Smith: Threaten to expose the conditions of his property in the public press — —

Bryant: Hm-m-m — —

Smith: Let me have three reporters — — I'll get action — —

Bryant: Right! Let's see if it works — —

(*Music: . . . Tag in and out . . .*)

Sound: Street noises

Smith: Here comes his carriage now. When he gets out — — go to work.

Voice 1: Watch us, Dr. Smith — —

Sound: Horses up to stop

Sound: Carriage door open and man getting out

Reporter 1: Ah — — Mr. Cooper — —

Cooper: Er — — yes.

Reporter 1: I'm from the *Evening Post*. Mr. Cooper do you have a statement to give us about your property on East 22nd Street?

Reporter 2: They call it a fever nest? What's your opinion, Mr. Cooper?

Reporter 3: Is it true that there is no provision made for the disposal of sewage in your tenement?

Reporter 1: How many people have died of — —

Cooper: What is the meaning of this?

Reporter 2: Just getting the facts for a newspaper story.

Cooper: Newspaper story? Uh — — ah — —

Smith: Mr. Cooper — —

Cooper: Dr. Smith. Please — — please — — come into my office with me.

Smith: What for?

Cooper: Ah — — er — — I've changed my mind about that tenement. Yes, indeed. I — — I'll renovate — — clean it up — — anything — — but please, Doctor — — call these men off! They musn't print a word!

(*Music: . . . Triumphant tag in and under . . .*)

Narrator: Stephen Smith's one-man crusade paid large and wholesome dividends. The glaring violations of the simplest principles of health that existed in the slum-centers of New York inspired a group of public-spirited physicians and laymen to take positive and immediate action — —

(*Music: . . . Out . . .*)

Smith: There's only one way to get the facts and prepare laws and measures to improve conditions — — an intensive, city-wide survey of conditions. I have called on you younger physicians to act as sanitary inspectors. The entire city has been divided into zones — — each one of you will be assigned to a single zone. Here's what we want! A complete, exhaustive report on conditions — — the number of people in each room — — the state of their health — — sanitary conditions — — each and

every fact bearing on the health of the individual. It will take time, money, effort. There will be only one reward — — a cleaner, better city. I ask for your coöperation. Do I get it?

Sound: Shout of many voices in affirmative as

(Music:..Tags solemnly and under..)

Narrator: The report of this sanitary inspection of New York City in 1865 is a classic, a masterpiece of stark, tragic, almost nauseating prose. A few excerpts — —

Voice 1: In 17 blocks, 55 houses contain 246 persons living in cellars completely underground — —

Voice 2: The mother, a wrinkled crone at thirty, sits rocking in her arms an infant with pasty and pallid features that tell that decay and death are usurping the place of health and life.

Voice 3: Sitting together upon the same broken box, lying together upon the same dirty straw, covered by the same filthy shreds, you have a picture of a mass of corruption and squalid misery gathered inside the walls of the unventilated building.

Voice 1: The attic rooms are used to deposit the filthy rags and bones that are taken from the gutters and slaughter-houses.

Narrator: Enough! But remember this — — these were not isolated conditions, found only in New York — — they were identical with the unsanitary, the fever-breeding, the death-nourishing melting pots of humanity found in almost every city of every nation on the globe. It was the result of an industrial revolution that forgot the human decencies. But times were changing. In 1865 — —

Voice 2: A Bill to promulgate a Metropolitan Health Law!

Narrator: Passed! Passed by the representatives of the people for the people's own protection! The repercussions of this triumph for municipal cleanliness were world-wide! Administered by intelligent, scientific authority, the health agency set up by the Metropolitan Health Law quickly justified its existence — — cholera disappeared from New York. Malaria, dysentery, typhus all were attacked — — all were vanquished! The death rate was halved — — halved again — — and in almost every city in the United States, the results of sanitation and regulated public health were paying tremendous dividends in human life. The Battle for Health was joined — — the issue was never in doubt!

(Music:...Up full, triumphantly and out)

Sound: Outdoor noises — — birds, etc. — — steady hum of automobile motor, broken occasionally as car bangs over a bump in road

Soper: Stop here, Bruce — —

Sound: Car up and out

Soper: (Calls) Hallo! (Pause) Hallo! Anybody around?

Wilson: It gives me the creeps, Fred — — a valley of ghosts!

Soper: (Sighs) Just about! Nobody around, I guess — —

Wilson: Probably all run off to the North — —

Soper: Not all — — look at those graves.

Wilson: Umm-m — —

Soper: (Cynically) The great and fertile valley of the Jaguaribe — — Brazil's inland empire! Look at it!

Wilson: Empty huts — — broken doors — —

Soper: And why? (Vicious slap) Because of this — a mosquito!

Wilson: Not just a mosquito, Fred — — give credit where credit is due — — a very special mosquito. Hail the Caesar of the insect world — — *Anopheles gambiae*! (Lowers voice) *Anopheles gambiae* — — dirty little devils! Come on — — lets get out of here!

(*Music: . . . Tag in and under . . .*)

Narrator: And this was not decades ago. This was 1938. 1938! Years after Pasteur had proved the germ theory — — Lister had demonstrated the power of sterilization — — Koch had discovered the tubercle bacillus and Ehrlich had reached the magic number of 606. Florence Nightingale had long passed away — — the names of Walter Reed and William Gorgas were in history. Landsteiner had typed blood and sanitary engineering was an honored profession. 1938! The scourge of typhus had almost disappeared from the earth — — cholera was driven back to the wild hills of Asia from whence it came — — diphtheria was conquered — — yellow fever was only a grey memory on the American continent — — the death rate from tuberculosis was slowly — — but surely — — falling! 1938 — — and an authority could still predict:

Voice: If *gambiae* malaria is not eradicated at once, a large part of Brazil and many other countries on the American continent face almost certain disaster!

Narrator: This was 1938!

(*Music: . . . Up dramatically and out . . .*)

Barreto: It is an interesting proposal you make, Dr. Soper — —

Soper: The reconnaissance trip Mr. Wilson and I have just concluded through the stricken area, Dr. Barreto, fully justifies these recommendations — —

Barreto: But complete species eradication — — that — — that is rather a startling thing. Ambitious — — perhaps too — —

Soper: One hundred thousand people have become affected — — about 20,000 have died — — since *gambiae* malaria entered Brazil! This specific type of malaria is rare and deadly — not the usual curable form of the disease. The only way to attack is to kill — wipe out — eradicate the source! And we can do it — —

Barreto: How?

Soper: We have a number of things on our side. One, the nature of the insect itself. Luckily, it's highly domesticated — — it only breeds near humans. We don't have to worry about it spreading in the unpopulous jungles and swamps of the interior.

Barreto: Yes — — that's true enough.

Soper: Second. we have some weapons at our command. The Yellow Fever Service that has so successfully controlled and eliminated that disease from Brazil can give us trained personnel.

Barreto: But the Service is hardly large enough to attempt species eradication of this mosquito.

Soper: Then we'll expand it! It will be expensive — — the Lord only knows how much it will cost — — but it must be done. I can only speak for the International Health Division of the Rockefeller Foundation. We are willing to contribute

money and time — — trained personnel and equipment.

Barreto: All right, Dr. Soper. I can speak for the government of Brazil. We will appropriate the necessary funds and make the suggested transfer of personnel from the Yellow Fever Service. When do you think we should start?

Soper: Now. Right now. And it's not one minute too soon!

(*Music: . . . Tag in and up and under . . .*)

Narrator: Now the combined wrath and genius of the Americas was turned on *Anopheles gambiae*. The spindly, brownish-yellow killer that had smuggled its way into the New World early in 1930, perhaps on a fast French destroyer, was the tiny object of the greatest man-hunt in modern history. The Malaria Service of the Northeast was not a haphazard collection of scientists, day laborers, and hangers-on! It was war — — and like all phases of modern conflict — — planning and organization preceded every move! The General Staff planned its strategy — — the cartographers made maps — — the engineers made surveys — — the intelligence made reports. Then — — only then — — the infantry went into action — —

(*Music: . . . Out . . .*)

Sound: Knock on door

Woman: (Off mike) Who is there?

Pablo: Disinfecting squad.

Woman: Oh — — come in.

Sound: Door open

Pablo: Good morning. Where is the bedroom?

Woman: Back there. My husband is still asleep.

Pablo: Umm-m. In here, men.

Sound: Footsteps — — door open

Sound: Deep snoring of man

Pablo: All right — — open the umbrella — —

Woman: Umbrella?

Sound: Umbrella opening

Pablo: Yes. We use it to catch mosquitoes. Watch how. First we open it. It is square, you see — — that is to make it easy to get into corners. Now — — over the umbrella, I use my spray gun loaded with insecticide — — like this — —

Sound: Flit gun

Pablo: You see — — the mosquitoes that hang on the roof and the walls fall into the umbrella. So.

Woman: Then?

Pablo: Then we gather all the mosquitoes — — put them in a box and send them to headquarters at Fortaleza. They examine them and see how many *gambiae* we have caught! That's how they know how to control the disease. You understand?

Woman: I — — — I think so. (Suddenly) Joao! Joao!

Joao: (Suddenly aroused) Eh? Ah?

Woman: We are being disinfected. Get up!

Joao: (Sleepily) Oh — — — — — Oh, yes. How do you do?

Pablo: How do you do. We are sorry to disturb you, sir. We will start with this room and then work through the house to the kitchen.

Joao: (Getting up and yawning) I am going to the kitchen — — —

Woman: To eat?

Joao: No ——— to sleep. (Yawns)
Wake me up when you get there.

(*Music:..Tag in and up and under..*)

Narrator: The disinfecting squads used insecticides in the homes and Paris green on every pool of open water they could find. Chief inspectors checked their work — and Post inspectors checked on them ——— it was an army of thousands battling an enemy of millions. Quickly the people of Brazil realized that here was a fight for their own existence. They changed from casual onlookers to active participants ——— it became a national crusade. And then the map began to reveal wonders!

Voice 1: December, 1939 ———
—— Gambiae has disappeared from
Cascavel and Quixada ———

Voice 2: March, 1940 ———
Gambiae has been driven out of Assu
and Ico!

Voice 3: May, 1940 ——— Gam-
biae has been eliminated from
Jaguaribe!

Voice 1: July, 1940 ——— Gam-
biae has disappeared from Coera
Mirim ———

(*Music:....Strong chord.....*)

Narrator: Back ——— back from
the interior ——— back almost
1,000 miles to the Atlantic Coast
—— the invader was driven!
By September, 1940 ——— two
years from the start of the campaign
—— *Anopheles gambiae* ———

scourge of Africa ——— was wiped
off the face of America. Gone
—— eradicated ——
finished! They said it could not be
done ——— and it *was* done!
Done by the united action ——
the united genius of the Americas!
Take pride in that —— all you
of America —— hear this, and be
proud. Gambiae malaria is gone
—— gone into limbo along
with typhus and cholera and yellow
fever! Will it return? Will the
other scourges return? There is only
one answer —— vigilance ——
constant, sleepless vigilance! In the
Battle for Health, all free people are
united! In the Battle for Health,
there is never a truce! Keep alert,
America —— keep strong and
ever healthy!

(*Music:...Sweep up full and out...*)

Narrator: This week —— in
New York City —— the War-
time Public Health Conference has
met the problems of disease control in
a battle-torn world. The manifold
difficulties of public health under
these conditions is being met by
united action and modern scientific
control! The public health officials
of the Americas and the United
Nations are the staff officers in this
eternal struggle for human life
—— they are the key men, the
pioneers in this never-ending crusade
for better health —— for a better
world!

(*Music:...Up full and out....*)

A NEW INTEREST IN CHEMOPROPHYLAXIS

HOPES for effective *prophylaxis* in relation to communicable diseases have undergone a sort of ebb and flow in the past fifty years, as has the use of the word itself. In the beginning of this century, prophylaxis was a somewhat generic term implying a shot-gun pattern of action where one relied upon many vague doings rather than upon any one specific procedure or agent. Aside from quinine, perhaps only the asafoetida bag was conceded specific prophylactic virtues. The latter went out of fashion a generation ago, but quinine retained its reputation as a malaria preventive for a long time, until the experience of troops in areas where malaria is endemic rather strongly emphasized to medical officers a fact already known to malariologists, to wit, that the so-called prophylactic use of quinine, or atabrine, does not really prevent malaria.

It may be said, then, that during the past few decades the tide of interest in specific prophylaxis has been strongly on the ebb. At the moment, however, there seems a modest flood of hope, in that reports of research and experience in the prophylactic use of sulfa drugs are now beginning to appear in scientific journals. One is encouraged to believe that these drugs may give definite protection against gonorrheal infection, and may sharply reduce the number of meningococcus carriers, presumably lessening the individual's likelihood of contracting the disease caused by that organism.

For the most part, experiences in the prophylactic use of sulfa drugs in relation to gonorrhea and meningitis have been in the military services where conditions for observation are much more favorable than in civilian populations. How effectively agents of this sort may be employed in extra-military health work remains a question. Scattered civilians are not in the same category as a concentrated military group, where individuals are given leave only at known intervals and are under rather rigid discipline and observation before and after that leave. It must be recognized, therefore, that in civilian life, and in relation to gonorrhea, exposures do not occur at intervals in a predetermined and somewhat periodic schedule but at various times, as the possibilities of a given situation develop. Certainly one could not go on a sulfa drug diet, just in case. In further

relation to chemoprophylaxis against gonorrhea, two other considerations would inevitably arise. First, from a medical standpoint there would be some danger in self-dosage; and, second, there would be objection by those who sincerely believe that to encourage prophylaxis would be to stimulate immorality and condone sin. On the other hand, potentialities for the application of antigonorrheal drug prophylaxis in civilian life are not to be brushed aside merely because of difficulties. It is a subject worthy of exploration along many lines: scientifically, administratively, psychologically.

In the meningococcus meningitis situation, there are not so many barriers to the use of a prophylactic drug in selected instances. It would not be possible, even if desirable in the face of an epidemic of meningitis, to give prophylactic doses of a drug to an entire local population, just as it is not practicable to provide a passive immunity for all susceptibles who might possibly have been exposed, say, to measles or diphtheria. But chemoprophylaxis would be practicable in situations where cases of the disease were occurring in somewhat segregated groups of individuals. Thus, in young men in dormitories and in similar domiciliary concentrations in which meningococcus meningitis tends toward a high prevalence, specific prophylaxis under medical direction would be a measure of great importance.

Regardless of whether or not there is a sound foundation for these early promises of the prophylactic effectiveness of sulfa drugs in the diseases mentioned, this new interest in chemoprophylaxis will undoubtedly stimulate research as to possibilities with other drugs and with other diseases, and will add a badly needed fresh note to the whole subject. At best, of course, this type of protection would be transient, not comparable to a previously established and continuing active immunity. But pending the development of new antigens, and particularly in the emergency of war, new explorations in chemoprophylaxis are more than justified. It might even result in the development of a real prophylactic against malaria which, from a military standpoint, is an outcome that might well change the fortunes of a campaign.

THE EXPANDING HORIZONS OF PUBLIC HEALTH

IT would be difficult today to discover an intelligent person with a social conscience who is unaware of the recent sessions of the Council of the United Nations Relief and Rehabilitations Administration and something of the public health significance of this global effort to meet the world's critical needs. Elsewhere in this issue will be found a condensation of those reports relating to health which have come out of the sessions in Washington and Atlantic City and which should supplement the general information which has already appeared.

Those who went through World War I and were involved in the post-war efforts toward relief point to the advantage in facing these needs in a broad and systematic manner before the military phases of the war are ended and with free access to the resources of the United Nations, both material and personal. Some lessons learned 25 years ago have already given relief efforts an important advantage in the present emergency. There is more orderly planning, there are better established channels of action between the nations, a greater facility in meeting the problems of nutrition and the prevention of disease than we have ever enjoyed, and a vastly expanded resource in trained and experienced public health workers.

It can be said with confidence that the leadership in Committee IV on Relief and Rehabilitation Policies and in the Sub-Committee on Policies with Respect to Medical Care is excellent. It is fortunate that the Director General of UNRRA is so able and experienced an administrator and one so familiar with good public health practice. Herbert H. Lehman, then Governor of New York State, speaking before the American Public Health Association in 1937, said "It is my firm conviction, often repeated, that so far as science and government can make it possible, an equal opportunity for health is the right of all citizens of the community, regardless of circumstances, birth, economic conditions, geographical limitations, race, creed, or color . . . definite plans require expert preparations and supervision, with official recognition of the maxim that the health of the people is indeed the highest law." Also, "That the economic condition of a community bears a very direct and potent relation to the health and welfare of its citizens is a conviction which has continued to grow upon me for many years."

These are heartening words from the Director General and he will have no unfamiliar teammate with whom to work out these policies for Dr. Thomas Parran is Chairman of the Sub-Committee on Policies with Respect to Medical Care of UNRRA.

Health workers in an international body like the American Public Health Association have a vital interest in the personnel which will be used for such a herculean task. The record to date of OFRRO, the former American counterpart of UNRRA, which was under Governor Lehman's direction, gives reason for hope that the choice of staff will be made on a merit basis and with a judicial balancing of the relative importance of technical training and an ability to get along with people. The sources which have so far been used indicate that the Governor means what he has said about the choice of the best available persons to do the job. That there will be difficulties and obstacles, no one can doubt. That it will be hard to maintain high morale in any group long after the demobilization of the military forces is obvious. Yet the readiness of highly qualified health men and women is a matter of record and should be encouraging to all concerned.

As a statement of policy for a newly established health agency, it would seem that the declarations with respect to health and medical care are admirable, "The reestablishment of health being one of the principal objects of relief work, it is essential that the status of the health organization should be commensurate with its importance in the work of the whole administration." It is emphasized that it is a recognized principle of administration that all work of a technical character should be carried out under technical direction. Since every aspect of the work of UNRRA will necessarily have health implications, the director of health must be afforded a position in the administration which will enable him under the authority of the Director General to develop suitable policies and to exercise proper technical direction over all health aspects of the work of UNRRA. What if each of our states and provinces were set up with a similar declaration! . . . "The status and success of UNRRA from the health point of view depend on obtaining the services of a director of health of the highest possible professional standing, whose previous work is such as to command the respect of those qualified to judge, both from the technical and administrative point of view."

For career workers in public health it must be conceded that these plans throw new perspectives around the task. To have the familiar technics and the experience of our daily work applied on a global horizon by those whom we regard as worthy of the high responsibility—that indeed is a challenge. There is no escape from

the obligation which each has to see his own part in this huge undertaking, whether abroad or at home, for if this work be well done it will have a profound influence on other international relations.

Viewed in the long perspective, UNRRA will facilitate the later development of a permanent, world-wide health organization and that may well be the framework on which an enduring international peace may be established.

Credit Lines

THE appreciative response which has arisen over Dr. Patterson's recent guest editorial "The Compleat (Annual) Reporter" (see October Credit Lines) has prompted the Editors to ask him to present another aspect of agency business, namely the writing of letters. The next voice you hear will be that of Dr. Raymond S. Patterson, Director of Health Education, John Hancock Mutual Life Insurance Company, Boston.

DO YOU NEGLECT THIS DEVICE?

Is this a fair picture of you, too?

Dr. Health Officer (or Miss Agency Executive) "with shining morning face" seats himself at his desk. His secretary brings in the first grist of mail.

Groaning loudly over the thickness of the pile, Dr. Health Officer takes up the letters and then there ensues the following monologue:

"This doctor wants some specimen containers. Refer the request to the lab., Miss Scribble. I'll answer the first part of his letter if I see him at the meeting next week."

"This woman really wants a baby booklet, I guess, but send her the other one about toddlers, too."

"Refer this request to the Welfare Association, please. Oh yes, and here's one for the Street Department Miss Scribble."

"Well, here's a letter I'll have to answer, I'm afraid." Reluctantly he begins to dictate: "Dear Mrs. Kantwayt . . ."

A tiresome inconsequential job to be gotten over quickly so as to get down to the important work of the day—such is office correspondence!

Is that your measured opinion Dr. Health Officer (or Miss Agency Executive)?

Each morning come these letters from people who want your advice, who seek information, who are in need of your services. They are coming to you for help, they are in a receptive attitude of mind, they are ripe for health education. If health education is influencing of the health habits and attitudes of the people of your community, then here is a golden opportunity to cast your bread upon the waters with an excellent chance that it will be returned to you—when you least expect it.

Don't neglect this opportunity. Instead, make the most of it. Answer questions in detail as though it were a pleasure to give the information. Let the writer know that his request for services will be complied with gladly, promptly, and completely. Then—when he is in a state of pleased surprise—say to him, "you may be interested to learn . . ." and in a couple of well-thought-out paragraphs tell him about the current health department activity that everyone in your community should know about. Public opinion is the combined opinion of individuals. You are molding public opinion in each letter.

SOMETHING ABOUT YOUR LETTER'S LOOKS

Often your letter is your first, sometimes your only, contact with your correspondent. Your representative deserves to be well dressed. You don't go, yourself, in overalls to meet your public, or allow your nurses to go in slacks and sweaters. Some letters that

I have seen—yes, from health agencies—are in about that state of undress.

Your letter should be as attractively clothed as you would be. A clean sheet of white paper of good quality, a letterhead pleasingly printed in legible type and in black or nearly black ink, your letter conventionally typed—with a new typewriter ribbon, please—in the center of the page, and with eye-soothing white margins all around. The recipient of your letter may not remember, but he glows with pleasure as he takes it from the envelope.

Some agencies—especially the tuberculosis associations—are addicted to “namitis.” You may find a list of ten, twenty, *thirty* names down the left margin of the paper. No one ever reads these names but the funereal border of black competes with, and detracts from, the message you hope your correspondent will read. Why make it hard for him to concentrate with such a sideshow? A few agencies go so far as to print messages here, with subheads in red, planned deliberately to compete with the letter itself!

What about “namitis”? If there is an impressive list of Nabobs who must be named, would it not be better to print the imposing array on the back of the letter? Then all the titles and positions may be appended as well, and everyone will be impressed. If there is a message that *must* go with each letter, could it not be enclosed as an envelope stuffer? If the idea is so all-fired important could it not be written into the letter? It should deserve that much attention.

SOMETHING ABOUT WRITING

If you propose to influence your correspondents' health habits and attitudes by words, then your words had better be sharp, clear, and compelling. All of us live under a deluge of words poured on us from the radio, the press, and our neighbors. The only way we

can keep our sanity is by learning to cover our minds with an umbrella of indifference. So, if you, Dr. Health Officer (or Miss Agency Executive) propose to pierce this umbrella with your words, make them good words.

Writing is a skill that grows with practice—in no way different from piano playing. Could you play even “Old Black Joe” without hours of practice? So if you would sharpen your words, whittle them with painstaking care. Make your letters models of persuasive writing. If you write good letters, you will be able to produce any other of the health educational media—with more practice.

Write critically. By that I mean, be critical of your own writing. Take time to re-write. Preferably sleep on your first effort—especially if it was dashed off in the fine white heat of inspiration—it may look a bit blue, next morning. Mrs. Shelley wisely said that the health educator should write, not so his writing can be understood, but so that it can't possibly be misunderstood. Take that to heart in your letter writing.

THIRTY-ONE STATES CONSIDER THEIR POST-WAR PUBLIC HEALTH PROGRAMS

Thirty-one state health officers are now in agreement with state plans for local health jurisdictions, arrived at jointly between them and the A.P.H.A. Committee on Local Health Units. It will be remembered that the committee exhibited maps and tabular data showing both the existing status and proposed plans for local health service at the St. Louis Meeting of the Association in October, 1942. This material, together with the minimum standards proposed by the committee, was summarized in the April, 1943, issue of the *American Journal of Public Health*.*

* Units of Local Health Service for All the States. Progress Report. *A.J.P.H.*, 33, 4:404 (Apr.), 1943.

The 31 states in agreement represent 58 per cent of the population of continental United States, have a total of 2,074, or more than two-thirds of all counties, and have agreed upon 749 units of local health jurisdiction, an average of nearly 3 counties per unit.

That this was not accomplished by mere formal and unthinking agreement with committee suggestions is eloquently attested by the fact that 21 of the 31 states as now districted have a different number and arrangement of jurisdictions from those suggested by the committee in the first instance. In 14, the number of units was increased upon recommendation of the state health officer; in 7 states the number decreased. However, the number of units agreed upon in the 21 states combined is fewer than the number suggested by the committee.

Even a superficial analysis of the correspondence and the supporting material furnished by state health officers to support their variations from committee suggestions indicates the extent to which this plan has stimulated the imaginative thinking of state health officers. Discussion revealed an acute awareness of local social, geographic, economic and political factors and maps, current population, and financial data were in most cases prepared. Unless all signs are misleading, the post-war world will feel the stirrings of a movement that is gathering a sure momentum. At that time personnel back from the wars will be available and the federal government will in all probability be prepared to assist localities in financing an adequately planned and staffed public health program. The states with a plan will have first call on personnel and funds.

This movement has implications for public health education in the medical, nursing, sanitation, and related fields. As the local health officer becomes the custodian of the public health of a con-

siderable body of citizens, his professional and economic status will be such as to justify special training for his responsibilities on the one hand, and to demand that he forego private practice on the other. Similar incentives will be present for professional training of the public health nurse and the sanitary engineer. Likewise colleges and schools of medicine, nursing, engineering, and social work will have a guide as to the number of professional personnel that will be required, as well as a fairly definite blueprint of the jobs to be done, and the financial rewards for adequate training and performance. Further, as public health jurisdictions become organized as now planned, they can serve as field work laboratories for the future training of workers.

FOR PHYSICIANS ONLY

The Subcommittee on Personal Health and Safety of the State Home and Farm Safety Advisory Committee, New York State Department of Health, is responsible for a concise, 8 page statement of the home accident problem in the state and the responsibility of the practising physician in reducing it. He is reminded of physical conditions and medications which may cause accidents, of situations which may cause trouble for infants and toddlers and of types of advice to give to mothers to prevent accidents.

"An outline of Public Health Activities for the Practising Physicians of Minneapolis," issued by the Division of Public Health, F. E. Harrington, M.D., Commissioner, is a sturdy, well printed book of 68 pages and cover. It is a straight-forward, factual, and readable account of the organization and activities of the division with "The Physicians' Participation in This Activity" concluding each section. Illustrations of forms for reporting communicable diseases and the list of reportable diseases are included in the chapter on

this subject. Several appendices make much useful and necessary information easily available for the physicians of the city. In these the existence and relation of public health activities at the federal, state, and local levels are summarized; the *International List of Causes of Death* is reproduced; some of the common communicable diseases are reviewed in a quick-reference table (one wonders why they were not arranged alphabetically); quarantine and isolation of communicable diseases and susceptibility tests and active immunizations are presented in tabular form. A final section deals with the scope of premarital examination laws in 33 states, lists of approved out-of-state laboratories and approved tests, license and residence restrictions, and sources of examination forms, and gives the periods of validity of examinations, laboratory tests and licenses.

THE HEALTH OFFICER MOVES OVER

It seems that for years the members of the West Virginia Public Health Association have been under the impression that their Constitution specifies that only a health officer may be elected to the office of President. There has been a growing dissatisfaction with the automatic ignoring of public health nurses and sanitarians which this general belief brought about. Recently the Executive Committee was stimulated by a health officer to search the Constitution and By-laws and discovered that the election of a health officer year after year to the Presidency was simply a matter of precedent. At the spring meeting, the association will vote upon an amendment which, if approved, will rotate the highest office so that a health officer, a nurse, and a sanitarian will each hold it once in every three year period. This may or may not be a good system, but that is not the point. The point is that things do not have to stay the way they are.

There is a good deal of encrustation of tradition in organizational set-ups, a corner of which might well be scraped off to see what is underneath.

KNOXVILLE AND KNOX COUNTY CONSOLIDATE HEALTH SERVICES

Credit Lines reprints by permission the following news note from the November issue of the *National Municipal Review* with congratulations to Knoxville and Knox County for taking this progressive step in such business-like fashion:

"A merger of the Knoxville Bureau of Health and the Knox County Health Department took place July 1 through a written contract entered into by city, county, and state officials. The contract can be terminated by any of the parties at the end of any fiscal year provided the terminating party gives sixty days' notice. Under the contract the city must appropriate to the consolidated department at least \$110,000 annually, the county a minimum of \$14,000, and the state must furnish in cash, materials, and service a minimum of \$70,000 a year.

Director of the combined department is the former Knoxville public health officer, Dr. W. H. Enneis; associate director is the former County Department of Health director, Dr. A. G. Hufstедler. The personnel of the city and county health departments were retained in the new department and classification and compensation for these employees will be established and maintained in accordance with a program approved jointly by the state and city civil service. Compensation of employees is not to be reduced below the salary schedule submitted to the State Health Department last May. New employees are to be selected subject to qualifications required under state and city civil service programs.

Prior to consolidation the city was spending approximately \$1.30 per capita

for public health activities, and the county was spending approximately \$.30 per capita. The consolidation has resulted in marked increases in expenditure and expansion of services, particularly in the rural areas where health services had been wholly inadequate."

MOTHER HAD A FINGER IN THESE

A joint project between the New York City Committee on Mental Hygiene and the Bureau of Child Hygiene of the New York City Department of Health, Leona Baumgartner, M.D., Director, has resulted in a series of 14 pamphlets on child guidance with emphasis on infant feeding. Some are for parents, and these are of two or four pages, written with the utmost simplicity and informality; some are for parents and staff; and some for staff alone. Number 1 is for parents and is headed briefly "Children Like To Eat." In easy, conversational style, maintained throughout, it elaborates the theme presented in its first paragraph:

"Good food, offered in a matter-of-fact way, without urging. There—as simple as that—are the main points in helping children to develop good eating habits."

Pamphlet No. 2 is for staff and discusses children's eating habits and instructs nurses how to instruct mothers so that good habits may be formed. This is the pattern throughout the series. The staff pamphlets provide scientific background, unencumbered by technical language, however, and instruction related to the information given the parent.

The method of development of the pamphlets is noteworthy, as Dr. Baumgartner has described it. "The staff workers, nurses and physicians," she said, "brought together the questions that they found mothers asked most frequently in baby health stations, and the problem with which they spent the most time. Preliminary drafts of pamphlets

which might be expected to help in a given case were then prepared. They were mimeographed and used for a year in individual stations. Numerous staff meetings, field investigations, etc., were the result, but out of them came, we believe, a very useful series of pamphlets."

FOUR LEVELS OF GOVERNMENT

As significant for public health workers as for the city managers he addressed at their 30th Annual Conference in Chicago on September 14, is this extract from Louis Brownlow's speech as published in *Public Management* for November:

"We must remember that this world is one world. We have got to think upward from the level of local government through four levels of government. Up to 30 or 40 years ago in this country any problem that came up from the people was first subjected to this question: Is this particular task to be entrusted to local government, state government, or federal government? And still nearly all our terminology, most of our everyday language, and a great deal of our ordinary thinking is shaped by that allocation of the responsibilities of governmental services among the three principal levels of government.

"But 30 or 40 years ago our actual practice began to change, so that today we no longer allocate an activity to one or another of the three levels of government in this country. We apportion a part of it to each of the three levels. We are not nearly so much the rivals in our several jurisdictional levels that we used to be. We are not fighting each other so much as our ordinary everyday language would indicate. We are witnessing the growing up in this country of coöperative government and in our most important activities we discover that all three of the levels of government are concerned with the

proper administration of those tasks that the people have decided are governmental in nature. When we realize that and can change our language so that it will come nearer to the actual fact we will have gone a long way to the solution of many of our most vexing managerial problems. No longer can these problems be answered in terms of *either federal or state or local government—it is and*. I am always amazed when I hear a local government official say he is hampered by the enmity of the state or federal government because he is fighting himself. For each one of us is a citizen of all three, and we are running all three, and all three are necessary in our national system.

"But now the three levels of government are not enough, because whether we like it or not, and whether or not our thinking is sufficiently adjustable and our language sufficiently elastic, we are a part of one world. How much you are going to accomplish with your plan in your city for highways, airports, and hospitals is going to be determined not by what you do in your city, not by what is done in your state capital, not by what is done in Washington—it is going to be determined in all parts of the world. What is done in China will have a repercussion on what is done in the United States, and vice-versa. What is done in Russia will have an effect on Australia; events in the South Seas will help determine the destiny of Canada."

WORTH ACQUIRING

For its persuasive reminder of how well off we are in the Western Hemisphere, the October 15 issue of *United States Municipal News*, published by the United States Conference of Mayors, 730 Jackson Place, Washington, D. C., which is devoted to "Local Government in Conquered Europe." Read it and rejoice that you are who you are and where you are.

The November issue of *Michigan Public Health*, published by the Michigan Department of Health, Lansing, H. Allen Moyer, M.D., Commissioner, for its article on "A Training Program for Replacement Sanitarians in Michigan" by John M. Hepler, C.E., Director of the Bureau of Engineering. This is the program which called forth the editorial published in *Credit Lines* for August from *The Ann Arbor News*. Mr. Hepler includes in his discussion the 3 weeks' course of study given at the University of Michigan and offers the plan as a solution of the sanitation problem in other states for the emergency.

"New Tools for Learning about War and Post-War Problems," a guide to films, pamphlets, and recordings for teachers, speakers, and discussion leaders, for its section on Achieving Victory on Home Front Problems which includes materials on health and welfare, juvenile delinquency and the school. Published by New Tools for Learning, 280 Madison Avenue, New York, N. Y.

"About Us and Our Friends" and "First Steps to Health Education," a guide to the former, published by the School Health Bureau of the Welfare Division, Metropolitan Life Insurance Company, New York, N. Y., for many suggestions to nursery, kindergarten, and primary school teachers concerning basic school health activities. The foreword to the guide by Donald B. Armstrong, M.D., credits Marjorie L. Craig and Grace T. Hallock with its organization under the guidance of Sally Lucas Jean and Julia Wade Abbott.

"The Proposed Program of Inter-American Activities" of the American Legion, for its framework upon which might be hung any program for community action. Published by the National Americanism Commission at National Headquarters, The American Legion, Indianapolis, Ind.

The August issue of *Tic*, published by Ticonium, 413 North Pearl Street, Albany, N. Y., for its bird's-eye view of the compulsory and voluntary sickness insurance programs in 38 countries. We have in mind a large bird with an enormous eye because 5 double-spreads of 14 columns each are required to present the data. The year of enactment, population, number of physicians and dentists, cost, administration of funds, cash and medical benefits, restrictions, and other information are given for each country.

WHAT IS BEING DONE IN ADULT EDUCATION?

A list of developments in the field of adult education prepared by a health educator presents a miscellany of interesting things which we have not seen brought together before. The list follows:

1. The U. S. Public Health Service has developed an experimental in-service program conducted for its own employees in health education. They have sponsored courses, workshops and scholarships in health education for teachers and there has been considered an extension of this work into a wider governmental field.

2. The U. S. Public Health Service has directed demonstrations in 90 southern areas on the use of teachers during the summer months for community education for malaria control.

3. A national nutrition program has had the participation of many government offices, state and local official and nonofficial agencies, and commercial organizations. This program has set an interesting pattern for the utilization of the resources of business for health education under government direction.

4. The Federal Public Housing authority has appointed a director of health education and is urging its project service advisers to assist in the development of health education programs in the housing projects.

5. An extensive adult education program through the Office of the Coördinator of Inter-American Affairs has been under way during the year in a very comprehensive way.

6. The National Safety Council and its

local affiliates have developed programs on safety education aided by industry, the War Production Board and other government agencies and the American Public Health Association are planning to extend safety programs through health departments.

7. Illinois has created a large, State-wide Public Health Committee to promote better understanding of public health in the governmental set-up. Similar committees have been under way in Nebraska, and California has sponsored local health institutes.

8. Illinois, Indiana, Oklahoma, and North and South Carolina, among other states, have initiated programs of training health education personnel for their health departments.

9. Local health education programs have been under way notably in Boston, New York, Hartford, Bridgeport, Detroit, and in local areas in North and South Carolina and Oklahoma.

10. The Cleveland Health Museum has developed numerous health exhibits for adults.

11. The planned Parenthood Federation of America has developed materials on family planning in relation to public health.

12. The American Film Center, Inc., New York, has developed a new and excellent annotated list of health films for lay audiences.

13. The American Public Health Association has published an official report on the Educational Qualifications of Health Educators as one of a series of standards for personnel in professional public health work.

The American Public Health Association has developed objective methods for the examination of public health nurses, health officers, public health laboratory workers and sanitarians, as well as methods for the examination of other specialists in public health work.

14. The National Tuberculosis Association, together with the North Carolina State Tuberculosis Association, has sponsored an institute for tuberculosis workers.

15. The Commonwealth Fund and the Institute for Inter-American affairs have granted health education Fellowships for adults.

16. The University of California School of Public Health is offering a special course in health education to meet the needs of Latin Americans.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Anopheles Gambiae in Brazil, 1930-40—By Fred L. Soper and Bruce D. Wilson. New York: The Rockefeller Foundation, 1943. 262 pp.

The events that transpired from March, 1930, when Shannon discovered *Anopheles gambiae* at Natal, Brazil, through the subsequent devastating epidemic of *Anopheles gambiae*-transmitted malaria, and culminating with the eradication of this dreaded vector following a carefully planned and executed control program, are well described in this important report. Included are sections devoted to the description of the imago, pupa, larva and egg of *A. gambiae* as well as pertinent information concerning its ecology. There is a detailed account of the region invaded and the subsequent spread of this transposed mosquito which came from Africa and multiplied at a prodigious rate in a very favorable climatic area, probably in the absence of most of its natural enemies.

The malarial epidemic that followed in the wake of the *gambiae* invasion in 1938 was as severe as any recorded when compared to the area involved. In the first half of that year there were at least 100,000 cases with a minimum of 14,000 deaths. Faced with the problem of interrupting the epidemic and stemming further spread of the mosquito, the health authorities of the Brazilian Government and The Rockefeller Foundation undertook a joint enterprise of species eradication.

A plan of organization is described which fortunately utilized the personnel facilities and experience of the Brazilian National Yellow Fever Service. Combined control measures designed to remove *A. gambiae* from

Brazil were instituted at the periphery of the area covering several thousand square kilometers and known to harbor the imported mosquito. Following a definite plan of attack which included anti-larval and adult spraying, disinsectization of all vehicles entering or leaving the area, and treatment, this border was pushed back so that by 1940 no specimens of the mosquito could be found and it was decided that there was no justification for the continuation of work. The remainder of the report is devoted to a thoughtful consideration of the problem of species eradication and the desirability of instituting similar efforts against the vectors of malaria in other areas rather than being satisfied with temporary control measures.

Few have had the opportunity or responsibility of deciding a course of action when a dangerous transmitter of disease breaks through its boundary and establishes itself in a new favorable area. Still fewer have had the foresight to plan a ruthless campaign and then remove bodily the last invader. That the last *A. gambiae* in Brazil has been destroyed seems well established, although even without new introductions there would remain some doubt for a few years until a definite statement could be made to this effect.

Unfortunately there is a factor that may mar the picture, namely, increased air transportation facilities from the endemic *Anopheles* area in Africa to Brazil. A doubt will be created as to the origin of any future wild-caught *A. gambiae* mosquitoes unless they should be found in large numbers in foci far from the port of entry. However, for the epidemiologist it is a clear-cut ex-

posé of what can happen when the world shrinks as the result of more rapid transportation, and for those concerned with the control of imported vectors or diseases it is an example of what can be done. No credit can be taken from this undertaking when it is stated that the habits of *A. gambiae* are such as to make them more easily destroyed by direct attack and that the production of other Anopheles of the Nyssorhynchus group rapidly returned to the pre-control levels at the termination of the campaign.

The successful methods and results of a never before tried large-scale campaign of species eradication as recorded in this concise, well written book will go down in the annals of major public health achievements.

L. T. COGGESHALL

Rheumatic Fever in Children—Its Recognition and Management—
New York: Metropolitan Life Insurance Company, 1943. 29 pp.

Rheumatic fever is assuming greater importance as reports come in from examination of draftees and a more searching analysis is made of vital statistics. Bureau of the Census reports reveal that rheumatic fever now heads the list of causes of death among children 5 to 14 years of age. It is also an important cause of disability and death in older age groups.

It is therefore timely that a trustworthy publication should be issued having the approval of The American Heart Association, The American Academy of Pediatrics, the U. S. Children's Bureau, and the U. S. Public Health Service. Outstanding authorities have contributed to the development of this helpful booklet. The importance and nature of rheumatic fever are well stated. In clear, concise paragraphs, the diagnosis, course, and prognosis are set forth. The sections on the care of the child and follow-up care

during the inactive stage are especially helpful. The publication is made more valuable by the appendices which describe the technical procedures for the examination of the heart, sedimentation methods, etc.

This booklet deserves wide circulation and should be placed in the hands of public health personnel as well as distributed to those engaged in clinical medicine.

RICHARD A. BOLT

Handbook of Tropical Medicine
—By *Alfred C. Reed and J. C. Geiger.*
Stanford University: Stanford University Press, 1943. 188 pp. Price \$1.50.

The authors have attempted to summarize the most important clinical, laboratory and preventive aspects of tropical diseases in this pocket volume of 188 pages. Such a task is extremely difficult and the authors have succeeded moderately well in their attempt. This book will serve a useful purpose for civilians and military physicians who do not have larger and more extensive works on tropical medicine available. Unfortunately there are no illustrations in the book which limits its use for those interested in the diagnosis of tropical diseases by laboratory methods.

The treatment of each disease is briefly covered and in general standard drugs and dosages are employed.

H. W. BROWN

Chronic Pulmonary Disease in South Wales Coalminers—II. Environmental Studies. *Medical Research Council. Special Report Series No. 244. London: His Majesty's Stationery Office, 1943. 222 pp. Price, \$3.00.*

This second report on chronic pulmonary disease in coalminers presents the results of the committee's attempt to measure the effects of certain environmental factors on the development of pneumokoniosis among colliers in the South Wales fields. Coal mining is not in itself considered a major cause

of silicosis, and it was believed that physical studies of the workers' environment and chemical and petrographic analyses of the dusts might throw further light on the etiology of pulmonary abnormalities found in this group.

On the basis of its investigations the committee concludes:

1. That the incidence of pneumokoniosis appears to be influenced neither by the temperature at the coalface nor by the humidity of the air.

2. That there is no correlation between the concentration of nitrous fumes from blasting and the incidence of pneumokoniosis.

3. That there is a significant association between the average mass concentration and the ash concentration of the dust and the incidence of pneumokoniosis.

4. That a relationship exists between the incidence of pulmonary abnormalities and the degree of metamorphism in the shales worked. Whether this is a direct relationship is unknown.

5. That while it is not possible to say that the quartz content of the dust is not the chief determinant of the pulmonary abnormalities found, the interaction of various other constituents must be considered in the etiology of the atypical form of pneumokoniosis found in this area.

Workers in the field of pneumokoniosis will be impressed by the authors' discussion of the question of what type of dust measurement best represents the hazard to workers exposed, and the relation between mass concentration and particle counts of the dusts. Equally pertinent is the caution that as a result of changes in methods of mining during the past twenty to thirty years present environmental conditions may now be very different from those under which the existing pathology developed. Although written for the technical worker this report is of interest to everyone concerned in the effects of environment on the development of pulmonary disease. ALTON S. POPE

A Study of Public Relations—By Harold P. Levy. With an introduction by Mary Swain Routzahn. New York:

Russell Sage Foundation, 1943. 165 pp. Price, \$1.00.

A Study in Public Relations, by Harold P. Levy, Research Associate of the Russell Sage Foundation, is, according to its own introduction, "the story of what has been done by one agency during a given period under a particular set of circumstances." Herein lie both its strength and its weakness. As a case study of the background, organization, and activities of the public relations division of the Pennsylvania Department of Public Assistance, Mr. Levy's book is informative. Students of social work interested in learning the set-up and specific problems facing a state-wide public relations program will find this book worth reading. Apart from its value as a documentary report of the Pennsylvania program, however, the volume has a limited appeal. Persons with even a passing acquaintance with the fundamentals of public relations will find few new ideas expressed in its chapters. The subject of newspaper releases, speeches, pamphlets, and other media are evaluated in a routine manner only. The importance of radio as a major instrument for moulding public opinion seems underestimated by the Pennsylvania Department of Public Assistance. Many of the findings relate exclusively to the particular project described and cannot be applied with any degree of accuracy to public relations projects in general.

Perhaps the greatest service provided by this book, aside from its value as a factual report on the Pennsylvania program, is the emphasis that it places on the importance of public relations "as a specific and definite function" for every large-scale social service enterprise. In convincing skeptics that even social service agencies can benefit from an aggressive public relations program, Mr. Levy's book makes a very real contribution, indeed.

FRANK A. CALDERONE

Annual Review of Physiology—
By James Murray Luck and Victor E. Hall. *Annual Reviews, Inc.*, 1943. 613 pp. Price, \$5.00.

If it is true that all health rules are good only so far as they conform to the findings of human physiology, then public health workers might as well make themselves more familiar with these findings.

Volume V of this *Annual Review* gives, in a very compact way, proven facts instead of the widely circulated beliefs and assumptions about the functioning of the human body.

Going along with the present trend there are many articles in the field of nutrition, such as: Energy Metabolism, The Digestive System, Liver and Bile, and Metabolic Functions of the Endocrine System.

The field of Physiology of Reproduction is covered by: Physiological Aspects of Genetics, Physiology of Mamalian Semen, and Endocrinology of Reproduction.

Other subjects reviewed in detail are: The Functional Psychoses and Physiological Correlates of Behavior.

Many experts have contributed, and the bibliographies are detailed and extensive.

BRUNO GEBHARD

As the Child Grows—By Helen Brenton Pryor, *New York: Silver Burdett Co.*, 1943. 400 pp. Ill. Price, \$3.00.

You, Your Children and War—By Dorothy W. Baruch. *New York: Appleton-Century*, 1942. 234 pp. Ill. Price, \$2.00.

Children Have Their Reasons—By Ruth Wendell Washburn. *New York: Appleton-Century*, 1942. 257 pp. Ill. Price, \$2.00.

In these books three well known teachers have echoed and interpreted much of the knowledge which intensive studies of children's growth and behavior have revealed in the past two

decades. All three emphasize the point of view that although there is a general pattern which can be expected of children of different ages, each child has his own individual pattern. However, the three authors tell their stories in quite different fashion.

Dr. Pryor tackles the problem in a direct fashion, discussing, from the more academic point of view, the factual knowledge which has been accumulated. Tables and charts are numerous. A carefully annotated bibliography is of particular value, but the short paragraphs on various medical topics, details of embryonic development, lists of 100-calorie portions, and other such more or less technical material, do not seem so. Such materials will probably interest the college student but the public health worker will probably find them a part of his background or wish fuller information.

Dr. Baruch has taken her knowledge of children and discussed the questions which parents, teachers, and others associated with them are asking in these war days: What can I do to help children and myself remain normal? What to tell children of hating, and killing, and democracy? Dr. Baruch's volume is timely, chatty and full of stories of how different individuals are solving these problems.

From the east coast comes the third volume, from the pen of one of the most beloved of children's "specialists," Dr. Ruth Washburn, who has always said she would never write a book about children. It is the belief of this reviewer that for years to come many will be grateful that Dr. Washburn finally decided she, too, had something to say. Here are the wisdom, humor, understanding, and kindness that Dr. Washburn has learned from children in the lifetime she has spent with them. And woven also into the fabric is the extensive scientific knowledge she gained in the 15 years she was

at the clinic of child development at Yale University. She is particularly adept in explaining children's ways to adults. Her technic of drawing illustrations from adult experience is peculiarly effective. The title of the volume, "Children Have Their Reasons," expresses the spirit of the presentation or, as Dr. Washburn says, "What parents need is not so much rules or behavior prescriptions—these may make robots of them. It is insight they need, and that selfishness which makes it possible to say each time a child's behavior is puzzling or irritating, 'If I were in his shoes, what would be my reasons, my excuses, my explanations?'" It is a volume that one reads and re-reads with joy and profit.

LEONA BAUMGARTNER

Managing Your Mind—By S. H. Kraines, M. D. and E. S. Thetford. New York: Macmillan, 1943. 374 pp. Price, \$2.75.

This book will likely appeal to the person of good education, rather than to the average person or the psychiatrically trained. There is good description of the advances in psychosomatic medicine and various types of purely psychological symptoms of the psychoneuroses.

Those readers who are familiar with Freudian literature may be resentful of the fact that some of the basic Freudian concepts are used as a basis for explanation of these symptoms but that the rôle of the unconscious is largely ignored or minimized. The description of various psychological mechanisms uses the exact terminology of psychoanalysis, but there is no indication of their Freudian origin, and the general impression left is that they are conscious mechanisms.

The leaving out of the rôle of the unconscious enables the authors to appeal to the intellect of the reader and leave the impression that an individual

can obtain conscious insight and control over his psychoneurotic symptoms. While the authors give adequate and repeated warning about self diagnosis and self treatment, the whole purpose of the book and the way it is written is to convince the lay reader that he can cure himself, so to speak. Since the major portion of the book is devoted to psychoneurotic symptomatology, one may be a bit pessimistic about the author's optimism in this direction.

In the latter part of the book, which is devoted to living a healthy life, the authors are on safer ground. In general their discussion of sex and marriage, a philosophy of life, intellectual objectivity, emotional maturity, self-reliance, and the use of one's energies represent good mental hygiene.

JAMES M. CUNNINGHAM

Housing Yearbook, 1943—Edited by Hugh R. Pomeroy and Edmond H. Hoben. Chicago: National Association of Housing Officials. 159 pp. Price, \$3.00.

This volume provides a useful handbook of housing developments during a year which witnessed the consolidation of sixteen federal agencies into one central body, the National Housing Agency. The problems confronting that agency—including the scheduling of new construction to meet the needs of war industry, the procurement of critical materials, and the control of occupancy to assure the housing of workers most in need of it—are reviewed by the National Housing Administrator, who points to the substantial accomplishment of a million and a quarter new housing units completed or scheduled under the defense and war housing programs up to March, 1943.

Activities of the three branches of NHA (Federal Public Housing Authority, Federal Housing Administration, and Federal Home Loan Bank Administration) are summarized by

their respective commissioners, and the administration of federal rent control by the Office of Price Administration is also reviewed. Not to be overlooked in any review of the national housing program is the rural work of Farm Security Administration, whose camps for migratory farm workers, combining shelter with programs of medical care, have been transferred to NHA but continue as an important factor in meeting the war housing need.

The Yearbook includes a useful directory of official and unofficial housing agencies, both local and national, with listings of their key personnel.

ALLAN A. TWITCHELL

Drying and Dehydration of Foods

—By Harry W. Von Loesecke. *New York: Reinhold, 1943.* 302 pp. Price, \$4.25.

The author has prefaced the book with the statement that its purpose "is an attempt to place before those interested in food dehydration a compilation of the latest practical information dealing with this subject. The data presented are not considered as giving a complete picture of the science of food dehydration. It was believed that the book would serve best if set forth without attempting an exhaustive treatment of the subject."

Chapter 1 is devoted to descriptions of the various types of dehydrators and a brief discussion of the important factors involved in drying. Chapters 2, 3, 4, and 5 present the methods used for the sun-drying and dehydration of fruits, dehydration of vegetables, eggs, milk, butter, meat, fish, and beef blood. Dehydration costs are analyzed in Chapter 7. Readers concerned with the public health aspects of the rapidly expanding food dehydration industry will be particularly interested in that portion of the text devoted to a discussion of Plant Sanitation, Nutritive Value of Dried and Dehydrated Foods,

and Packaging and Storage. The final chapter deals with Methods of Analysis, and Reconstitution of Dehydrated Foods.

The purpose of this book has been accomplished in that it is a well prepared compilation of much of the recent practical information regarding the drying and dehydration of foods. Suggested readings listed at the end of each chapter and references included in the text form a bibliography for those who desire detailed information on any particular phase of the subject. A partial list of patents pertaining to dehydration of foods is given.

In view of the importance of inert gas packing as a means of protecting certain dehydrated foods, such as dried whole milk, carrots, and cabbage, it would have been well to have discussed the factors involved in gas packing, and to have presented a more critical evaluation of the effectiveness of the various methods which have been proposed for commercial use.

The text contains the statement that whole dry milk is packed in 1, 5, 25, and 50 pound cans which are evacuated, the vacuum replaced by nitrogen, and the containers then vacuum sealed. We presume that the author intended to state that the containers are hermetically sealed rather than vacuum sealed, since the nitrogen filled cans are sealed hermetically at atmospheric pressure.

A brief discussion of the difficulties peculiar to the gas packing of whole dry milk would have been a valuable addition to the practical information given regarding the packing of products of this type. Although a glossary has been included, it appears to be composed chiefly of terms previously explained in the text.

H. L. SIPPLE

Sanitary Products. Their Manufacture, Testing and Use—By Leonard Schwarcz. *New York: MacNair-Dorland, 1943.* 287 pp. Price, \$5.00.

The purpose of this volume is to compile and discuss under one cover a few of the many aids used by man to promote sanitation and thereby reduce the spread of disease. The chapters are complete in themselves, each covering a distinct product or subject.

The author introduces his subject with a chapter on the history of bacteria which sets the stage for the later chapters on their control with disinfectants, insecticides, soaps, waxes, and the like. He defines such words as

"germicidal" and "bactericidal." Insects, roaches, bedbugs, moths, and many other pests are discussed.

The author's method of presenting the subject emphasizes its importance to human beings and to their economy, and produces a desire on the part of the reader to become more familiar with these combating agents. The book is written in such a manner as to be of interest to laymen as well as to those engaged professionally in this work.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Principles vs. Practice in Milk Testing—An inquiry was made into the practices of certain milk testing laboratories. Among those under scrutiny, none met all the "standard methods" requirements on equipment and procedure. Practically every item was violated by some laboratory sufficiently to influence the accuracy of the analysis, though every item was adhered to by several laboratories. Among the 168 items relating to plate counts the mean deviation was 32. Two more reports upon other phases of this study are to come: they should make equally interesting reading.

BLACK, L. A. Surveys of Milk Laboratories in War Areas in the United States. *Pub. Health Rep.* 58, 44:1605 (Oct. 29), 1943.

Vaccinia from Chick Embryos—Vaccine cultivated for 9 years on chick embryos induces a milder lesion than calf virus, but there was found no substantial difference in the degree of immunity attained.

BUDDINGH, G. J. The Pathogenic and Antigenic Properties of Dermal Vaccinia Virus Propagated in the Chorio-Allantois of Chick Embryos. *Am. J. Hyg.* 38, 3:310 (Nov.), 1943.

Chicago Intensive Treatment Center—In this preliminary report upon 931 patients given fever-chemotherapy for syphilis, the safeguards which should be applied to the intensive methods are described.

BUNDESEN, H. N., *et al.* The Intensive Treatment of Gonorrhea and Syphilis. *J.A.M.A.* 123, 13:816 (Nov. 27), 1943.

Quote—I've found the best way to bring a shadow of warmth into an editor's jaundiced eye is to show him

good glossy pictures—and then mildly suggest there might be a story with them. Unquote.

COOK, B. I Like My Job! *Pub. Health Nurs.* 35, 11:634 (Nov.), 1943.

Social Medicine—Fighting Words—Our United States and Canada are the only countries in which organized medicine has itself set under way health insurance plans under its own auspices. So begins a review of the schemes created by the medical societies. This is a continued story and some of it is "writ sarkastick."

DAVIS, M. M. Health Insurance Plans under Medical Societies. *Med. Care.* 3, 3:217 (Aug.), 1943.

Here Is News—After years of discussion about the possibilities of preventing caries by the addition of fluorine to the water, something is to be done about it. So take off your hats to these brave pioneers. Two cities with comparable populations have been selected. To one water supply sodium fluoride will be added and dental examinations will be conducted in both communities.

DEAN, H. T. Domestic Water and Dental Caries, (and) AST, D. B. A Program of Treatment of Public Water Supply to Correct Fluoride Deficiency, (and) WOLMAN, A. What Are the Responsibilities of Public Water Supply Officials in the Correction of Dental Deficiencies? *J. Am. Water Works A.* 35, 9:1161 (Sept.), 1943.

Games, Athletics, Out-door Activities, et al.—Canada, too, proposes to go in for physical fitness in a large and official way. A map of the highways to health is furnished.

HEAGERTY, J. J. The National Physical Fitness Act. *Canad. J. Pub. Health.* 34, 10:465 (Oct.), 1943.

Where Accidents Vie with Disease—Before the war there were five million Americans enjoying major or minor orthopedic impairments. What the number will be this year is anyone's guess. Rates for age and sex are given.

KARPINOS, B. D. The Physically Handicapped. Pub. Health Rep. 58, 43:1573 (Oct. 22), 1943.

For TB Case Finders—This item will interest only those who are actively concerned with mass chest x-raying and probably all such will have seen the original article, but just in case they haven't, it is about a gadget which times the exposure resulting in a saving of labor, and fatigue.

Slaves of Fashion—Does public health concern itself with the matter of up-swept hair-do's? If so, here is an account of some unfortunate ladies who developed a most unpleasant dermatitis because they tried to varnish their stray locks in place.

SCHWARTZ, L. An Outbreak of Dermatitis from Hair Lacquer. Pub. Health Rep. 58, 44:1623 (Oct. 29), 1943.

Diphtheria in England—Before immunization in England one child in 10 contracted diphtheria; one in 200

died. Though the proportion of immunized children is still far from satisfactory, there is much to be thankful for today, for the risk of an immunized child contracting diphtheria is 12 times less than for an unprotected infant, and the risk of his dying is more than 100 times less.

SCOTT, J. A. Diphtheria: 1. Administrative Aspects (and two related papers). Pub. Health. 57, 2:14 (Nov.), 1943.

How the Master Race Is Fed—Everyone who is interested in learning how well the German civilians are fed, will find factual material here based upon on-the-spot studies up to May, 1942, and from information received since. As you may surmise they are not eating heartily.

ASSOCIATION NEWS

PAN AMERICAN HEALTH DAY CELEBRATED BY THE COMMITTEE ON PROFESSIONAL RELATIONS WITH LATIN AMERICA

Commemorating Pan American Health Day, December 2, a "Health Charter for all the Americas" was dispatched to the capitals of all the American republics by the Association. Printed in English, Spanish, and Portuguese, and bearing the signature of Dr. Louis I. Dublin, Chairman of a newly appointed Committee to develop professional relations with Latin America, the Charter declared:

"We believe there are many ties that bind the Americas together beyond the accident of geography.

"High among these is the common purpose of the public health workers of all the Americas.

"United as we are in the timeless war against tyranny, so we unite now in the timeless war against disease, privation, and death.

"We unite to prevent the invasion of the Western Hemisphere by the plagues which ride behind the horsemen of war and famine.

"We unite to banish forever from our lands the diseases that have always been the heritage of mankind.

"We unite to fight malnutrition, ignorance, and all human misery.

"We unite in a scientific brotherhood of all the Americas to fight for that bright future possible only to happy, healthy peoples."

In a statement released to the Latin American press, Dr. Dublin stated that "the purpose of this committee is to encourage and develop in every practicable way cordial relations between workers in the field of public health in the United States and Canada and their colleagues in the Latin American countries. Especially at this time is it desirable to establish the closest ties of collaboration when the various countries of the North and South are engaged in a common effort to maintain the health standards of their people at high levels and to increase the common effort toward victory."

Dr. Ernest L. Stebbins, Health Commissioner of New York City (left) receiving a copy of the Health Charter from Dr. Dublin

Office of the Coördinator of Inter-American Affairs, 444 Madison Avenue, N.Y.C. 22

"The American Public Health Association," Dr. Dublin said, "has always been a clearing house for sound principles of health work. It has also served as a rallying point for closer personal relations within the profession. It hopes through its new committee to widen its sphere of influence to be equally useful in the Latin American countries. The committee proposes to explore the possibilities of an interchange not only of materials and information but also of professional workers to enable both parts of the hemisphere to share in the most recent public health practices and procedures."

"The Association through its Committee," Dr. Dublin declared, "dedicates itself toward these objectives and looks forward to increasing benefits to health work in both continents."

The members of the committee are:

Louis I. Dublin, Ph.D., *Chairman*, Third Vice-President and Statistician, Metropolitan Life Insurance Company, New York, N. Y.
Robert S. Breed, Ph.D., Chief, Division of Bacteriology, New York Agricultural Experiment Station, Geneva, N. Y.

Professor Gordon M. Fair, Professor of Sanitary Engineering, Harvard University, Cambridge, Mass.

Henry E. Melency, M.D., Hermann M. Biggs, Professor of Preventive Medicine, College of Medicine, New York University, New York, N. Y.

Nathan Sinai, Dr.P.H., Professor of Hygiene and Public Health, University of Michigan, Ann Arbor, Mich.

Ernest L. Stebbins, M.D., Commissioner of Health, New York, N. Y.

Clair E. Turner, Dr.P.H., Professor of Public Health, Massachusetts Institute of Technology, Cambridge, Mass.

The "Health Charter for all the Americas" was sent in duplicate with the request that the responsible health official in each country affix his signature to a copy and return it to the Association in New York as subscribing to its principles.

PROPOSED VITAL RECORDS ACT

The Executive Board of the American Public Health Association has approved the following resolution relative to the proposed Vital Records Act (S. 1096):

RESOLVED: That the Executive Board, on behalf of the American Public Health Association, hereby approves in principle U. S. Senate Bill 1096, subject to any improvement in the language which would clarify the purpose of the Bill and meet current objections, and which might be considered during the course of the forthcoming hearings.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

J. Shirley Hodges, M.D., 3800 University Park, Dallas, Tex., City of University Park Health Officer

Hernan San Martin-Ferrari, M.D., 615 N. Wolfe St., Baltimore, Md., Provincial Chief of Public Health Service of Antofagasta, Chile

Lester S. McLean, M.D., Vallejo Health Center, 228 Napa Rd., Vallejo, Calif., Director, Vallejo and Solano County Health Dept.

William A. Newton, M.D., 1149 Pearl St., Beaumont, Tex., Jefferson County Health Officer

Laboratory Section

Donald L. Augustine, Sc.D., Harvard Medical School, 25 Shattuck St., Boston, Mass., Assoc. Professor of Comparative Pathology and Tropical Medicine

Sgt. Beryl F. Capps, 37th General Hospital, APO 763, Postmaster, New York, N. Y., Bacteriologist

Gladys M. Craig, M.Sc., 170 East End Ave., New York, N. Y., Bacteriologist and Parasitologist, Doctors Hospital

Archibald M. Fitz-Randolph, 1618 A St., Portsmouth, Va., Asst. Sanitarian, U. S. Public Health Service

George E. Foley, 2 Primus Ave., Boston, Mass., Bacteriologist, House of Good Samaritan and Dept. of Preventive Medicine, Harvard Medical School

Frances J. Pain, 208 13th St., Pacific Grove, Calif., Junior Laboratory Asst., 9th S. C. Laboratory, Presidio of Monterey

Lt. Albert M. Reiss, Sn.C., Station Hospital, Mitchell Field, N. Y., Asst. Laboratory Chief and Asst. Base Sanitary Officer, U. S. Army

Lt. Joseph F. Ruiter, M.D.T.S., Lawson General Hospital, Atlanta, Ga., Instructor, Medical Dept., Technical School, Army of the U. S.

Major Leonard B. Solomon, M.C., 12th Hospital Center, Camp Gruber, Okla., Chief of Laboratory Service

Corp. Edward Stern, 967th Medical Hospital Ship Platoon, Camp Kilmer, N. J., Laboratory Technician

G. Fred Townsend, 905 W. Central Ave., Princeton, Ill., Asst. Chemist, Green River Ordnance Plant

Vital Statistics Section

Marian Champenois, 7325 St. Charles Ave., New Orleans, La., Tabulation Equipment Supervisor, U. S. Public Health Service

Andrew T. Court, 13-165 General Motors Bldg., Detroit, Mich., Employee Health Analyst, General Motors Corp.

Manuel F. Recao, Este 14, No. 12, Caracas, Venezuela, S. A.

Engineering Section

Jose F. Henriques, Rua Otavio Correa, 95, Rio de Janeiro, Brazil, S. A., Engineer of Public Health, National Dept. of Public Health

Jose R. Leon, Williams 25, Santurce, Puerto Rico, Asst. Professor in Sanitary Engineering, School of Tropical Medicine

Abbot A. Sackheim, Room 720, Reisch Bldg., Springfield, Ill., Sanitary Engineer, State Dept. of Public Health

Industrial Hygiene Section

H. Irving Dunn, M.D., Station Hospital, Raritan Arsenal, Metuchen, N. J., Post Surgeon

Major Everett W. Probst, M.C., Picatinny Arsenal, Dover, N. J., Industrial Medical Officer and Surgeon, U. S. Army

Capt. Max N. Pusin, M.C., Co. "A", 91st Medical Gas Treatment Bn., Camp Livingston, La.

Jean E. Wolfson, M.D., 134 West 13th St., New York 11, N. Y., Health Officer in training, New York City Dept. of Health

Food and Nutrition Section

Louis C. Barail, M.D., D.D.S., 1415 Park Ave., U. S. Testing Co., Inc., Hoboken, N. J., Chief Bacteriologist

Dr. Emilio Messner, Rafael Pastoriza 1564, Montevideo, Uruguay, S. A.

Ruth C. Steinkamp, M.S., Vanderbilt University School of Medicine, Nashville 4, Tenn., Junior Nutrition Consultant, State Health Dept.

Maternal and Child Health Section

Eva F. Dodge, M.D., 501 Madison Ave., New York 22, N. Y., Obstetric Consultant and Assoc. Medical Director, Planned Parenthood Federation of America

Jerome L. Kohn, M.D., 50 West 96th St., New York 25, N. Y., Assoc. Pediatrician, Mt. Sinai Hospital

Public Health Education Section

Garnett M. Cooper, 247 Kimbrough St., Memphis, Tenn., Unit Supervisor, Tennessee Dept. of Public Welfare

Emily C. Keefie, M.A., 1710 Prospect Ave., Cleveland, Ohio, Health Education Executive, Cleveland Y.W.C.A.

Lt. Col. Thomas T. Mackie, M.C., 6817 Georgia Ave., N.W., Washington, D. C., Exec. Officer, Tropical and Military Medicine, Army Medical School

Wade T. Searles, M.A., 82 N. High St., Columbus 15, Ohio, Field Representative, American Social Hygiene Assn.

Howard Strong, 1615 H. St., N.W., Chamber of Commerce of U. S., Washington 6, D. C., Special Representative, Health Advisory Council

Public Health Nursing Section

Martha P. Langley, 319 W. 8th St., Erie, Pa., Director, Visiting Nurse Assn.

Mrs. Cora Hoop Liere, R.N., 1210 Sheridan Drive, Danville, Ill., Director of Nurses, Child Welfare Assn.

Guillermina Rivera-Valles, R.N., Catholic Univ. Sch. of Nursing Education, Washington, D. C., Student

Epidemiology Section

Edward L. Benjamin, M.D., 2021 Grand Concourse, New York, N. Y., Epidemiologist and Borough Chief, Bureau of Preventable Diseases, City Dept. of Health

Sally C. Preas, 279 W. 12th St., New York 14, N. Y., Research Assistant, Milbank Memorial Fund

School Health Section

Howard S. Hoyman, M.A., Univ. of Oregon, Eugene, Ore., Assoc. Professor of Physical Education

Unaffiliated

Sigmund L. Friedman, M.D., 3411 Steuben Ave., New York 67, N. Y., Asst. Director, Montefiore Hospital
Brig. Gen. Morrison C. Stayer, Panama Canal Health Dept., Balboa Heights, Canal Zone, Chief Health Officer and Surgeon, Caribbean Defense Command

DECEASED MEMBERS

Walter W. Council, M.D., Juneau, Alaska, Elected Member 1933, Health Officers Section

W. Brownley Foster, M.D., Richmond, Va., Elected Member 1908, Elected Fellow 1923, Health Officers Section
Robert W. Kehr, Seattle, Wash., Elected Member 1934, Engineering Section
John Harvey Kellogg, M.D., Battle Creek, Mich., Elected Member 1878, Food and Nutrition Section
James R. McEachern, M.D., Tampa, Fla., Elected Member 1932, Elected Fellow 1936, Health Officers Section
J. F. Nickerson, Chicago, Ill., Elected Member 1912, Food and Nutrition Section

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

Physician: public health pediatrics. To assist director of maternal and child health in large California county health department. Major duties, conducting of infant and preschool health conferences and school examinations. Beginning salary \$350 and travel allowance. California license required. Training and experience in pediatrics or public health or both. Immediately available. Address William C. Buss, M.D., Kern County Health Department, Bakersfield, Calif.

Wanted: A physician trained in tuberculosis to assume administrative control of the Bureau of Tuberculosis in an eastern city of 200,000 population. Salary \$3,900-\$4,500 plus cost of living adjustment. Address Box B, Employment Service, A.P.H.A.

Sanitarian wanted: Preferably with Bachelor's degree or engineering degree, plus public health experience or training. Must have own car. Applicant with lower qualifications will be offered an opportunity to take a short, free indoctrination course. Salary \$1,920 per year with travel allowance of \$50 per month, if qualified. Apply Dist. Dept. of Health, No. 6, Central Office, Newberry, Mich., Dr. Franklin.

Wanted: Pediatrician to supervise medical care of children at cerebral palsy center being established by private institution in coöperation with Illinois Division of Services for Crippled Children. Salary commensurate with experience and training. For further information write Lawrence J. Linck, Director, Division of Services for Crippled Children, 1105 So. Sixth St., Springfield, Ill.

The Department of Health, New Jersey, whose industrial health activities have expanded rapidly during the present war, has announced its need for two full-time industrial hygiene physicians for its Industrial Hygiene Service. As one of the leading states in the production of war materials, New Jersey offers unusual opportunities for gaining experience in

occupational disease control besides giving the physician a chance to make a valuable contribution to the war effort. The principal duties of the selected physicians will be consultations in regard to the following: control of occupational diseases; industrial toxicological problems; evaluation of adequacy of plant medical services; promotion of measures which will reduce absenteeism from non-occupational causes; and conduct of industrial health education activities. Physicians interested in these positions should write to the Department of Health, Trenton, N. J.

Merit System for Personnel Administration in Delaware will set examinations for 3 positions in the Delaware State Board of Health shortly. The positions open for examination, together with the beginning salaries, are: Deputy State (County) Health Officer (\$3,800), Pediatrician (\$3,600), and Medical Social Consultant (\$2,400).

These examinations will be unassembled, but successful candidates will be expected to appear in Delaware for an oral interview which will be a weighted part of the examination. Appointments may be expected soon after the examinations are conducted.

Information and specifications as prepared for each position may be secured by communication with the Merit System Supervisor, P. O. Box 1911, Wilmington, Del., and application for examination must be made on the official form.

The Milwaukee Health Department is interested in obtaining an instructor in hospital nursing to conduct a student educational program in its communicable disease hospital. Salary offered begins at \$125 per month with maintenance, and increases of \$5 per month each year until \$135 has been reached. To this basic salary there has been added a cost of living bonus of \$30.64 per month, making the total beginning salary \$155.64 plus maintenance. Apply to Dr. G. F. Burgardt, Deputy Commissioner of Health, Milwaukee, Wis.

Wanted: Public health physicians in Texas. George W. Cox, M.D., State Health Officer, Austin, Tex.

Wanted: Public health statistician for large California County Health Department. College degree with training in statistics. Salary \$200. Position open. Address William C. Buss, M.D., Kern County Health Dept., Bakersfield, Calif.

Hawaiian Territorial Board of Health seeks trained engineer to supervise rodent plague control program. Salary range from \$331.67 to \$398.33 per month subject to retirement deductions plus bonus. Position under Territorial civil service system with classification of P-4. For further details address A.P.H.A. Employment Service.

Wanted: Physical therapist by crippled Children's Division. Should be graduate of a school of nursing or of college, with a major in physical education or science; have completed a course in physical therapy; should have had experience in physical therapy, preferably with children. Write for application blank to Merit System Council, 416 Henry Building, 309 S.W. 4th Ave., Portland 4, Oregon.

Psychiatric case worker desired for mental hygiene clinic, Department of Health, Peoria, Ill.

Senior Sanitarian, Alaska Health Department. Minimum requirements 2 years college, 6 months public health course, 2 years' experience. Two additional years' experience acceptable instead of each year college. Monthly salary \$235-\$265. Mary B. Pool, Alaska Merit System, Juneau.

Michigan announces civil service positions now open for orthopedic public health nurse, Grades II and III classes with the Michigan Crippled Children's Commission. Salary range: Grade II \$230 to \$270 per month; Grade III, \$280 to \$340 per month. Grade II not under 23, Grade III not under 25. Must have completed course in orthopedic nursing or physical therapy in approved school. For Grade III position a full-time course of at least 9 months' duration is required. Must have 3 years' experience in public health nursing, one year of which shall have been in supervisory capacity. For Grade III position one additional year of nursing and one additional year of supervisory experience required. Eligibility for certificate in public health nursing and registration as a nurse in Michigan. For further information write Michigan Civil Service Commission, 310 No. Grand Ave., Lansing 4, Mich.

Industrial Hygiene Toxicologist. Calls for person of chemical or chemical engineering background. Position, supervising of chemical work of industrial hygiene service and industrial hygiene laboratory; designing special apparatus for field studies on occupational disease problems; conducting field and laboratory analyses of toxicological exposures in industry; keeping records, interpreting results and preparing records. Requirements, knowledge of chemical laboratory methods and equipment; procedures for qualitative and quantitative analysis of organic and inorganic chemistry; knowledge of chemical methods of determining toxic materials in industry; familiarity with petrographic methods of mineralogical analysis. Immediate temporary appointment will be made, to be followed later by civil service examination to determine permanent status. Salary \$2,900 base, plus \$100 a year war adjustment, or total of \$3,000 per year. Travel expenses also allowed. Must be U. S. citizen. Resident of any state may apply. Write J. Lynn Mahaffey, M.D., Director of Health, State Department of Health, Trenton 7, N. J.

Vacancies in the Illinois State Department of Public Health will be filled from the eligible registers resulting from Civil Service examinations now on call for Bacteriologist, Laboratory Technicians and Serologists. January 14 is the last day for the receipt of applications in the Illinois Civil Service office, Room 501, Armory, Springfield.

Salary ranges for these positions are—Bacteriologist I, \$150-\$190 per month; Bacteriologist II, \$180-\$225 per month; Bacteriologist III, \$180-\$225 per month; Bacteriologist IV, \$300-\$375 per month; Laboratory Helper, \$100-\$125 per month; Laboratory Technician I, \$110-\$140 per month; Laboratory Technician II, \$130-\$170 per month; Serologist I, \$150-\$190 per month; Serologist II, \$180-\$225 per month. Applicants must be legal residents of Illinois.

Persons now accepting employment in the Illinois State Service have the advantage of a "career service" system, whereby persons with the minimum of training and experience can enter the beginning positions and through service ratings and promotional examinations can advance to top positions in the field. An additional inducement to attract qualified employees is the newly enacted pension plan offering retirement and disability benefits to all state employees.

The examination will be given at various centers throughout the state immediately after the closing date, January 14.

Application blanks, position descrip-

tions and qualifications required can be obtained by writing to the Illinois State Civil Service Commission, Room 501, Armory, Springfield, Ill.

Wanted: Sanitary engineer or chemist to assist in stream pollution survey and later in study of sewage treatment. Should be qualified to perform chemical and bacteriological analyses of water and sewage and chemical analyses of industrial wastes. Nine months employment beginning as near January 1 as possible, with possibility of indefinite continuation, particularly if person is willing to do some other types of analytical work, including coal analysis. Salary \$175-\$250 per month depending on qualifications. Women considered. Address communications to Prof. Gilbert H. Dunstan, Dept. of Sanitary and Public Health Engineering, University of Alabama, Box 1996, University, Ala.

Wanted: Senior assistant serologists for immediate employment in New Mexico Public Health Laboratory, Albuquerque. Bachelor of Science degree and 1 year experience as serologic assistant in laboratory of recognized standing required. Starting salary \$145 per month. Women or draft exempt men preferred. Address Dept. of Public Health, Box 711, Santa Fe, N. M.

Wanted: Public Health Nurse. Salary \$175 per month and full maintenance, plus \$25 per month for car expense. Must furnish own car. Write Paul D. Crumm, M.D., Director Boelne Tuberculosis Hospital, Evansville 12, Ind.

City of 70,000, southeastern U. S., seeks qualified health commissioner between the ages of 30 and 45, draft exempt. Salary \$4,500 plus auto allowance of \$300 per year. Box V, Employment Service, A.P.H.A.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK 19, N. Y.

In view of the current active demand for trained and experienced persons in public health, it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

ADMINISTRATIVE

Physician, age 37, M.D. Iowa, Dr.P.H. Harvard, specializing in tuberculosis, seeks position as medical director of a sanatorium or a state bureau of tuberculosis. Exempt from military service. **A-476**

Physician, M.D. Yale, with private practice industrial medicine. Age 39 and draft exempt. Seeks opportunity as public health physician. **A-505**

Physician, age 28, M.D. Yale, trained in pediatrics, now county health officer of southern state, seeks administrative position in northeastern United States. **A-509**

Woman physician, age 35, M.D. University of Minnesota, 2 years' experience as county health officer, seeks clinical or administrative position, preferably South. **A-510**

Woman physician, well prepared in pediatrics. M.S.P.H. DeLamar Institute, Columbia University 1943, seeks employment in field of maternal and child health, preferably administrative in pediatrics. Excellent references. **A-507**

Physician, M.D. University of Arkansas, M.P.H. Harvard, experienced as county health officer. Age 35. Will con-

sider position as county or city health officer or director of a bureau. **A-506**

HEALTH EDUCATION

Woman with background of health education and public health nursing, experienced as teacher, supervisor, and writer, seeks teaching position of responsibility. **H-507**

LABORATORY

Research bacteriologist. Unusually trained and experienced woman bacteriologist and serologist now occupying responsible position in state laboratory seeks research work of permanent character. **L-468**

Water chemist, bacteriologist, M.S. degree in Sanitary Chemistry. Age 36, draft exempt. Eight years' experience in state laboratory working on water, milk and sewage. Prefers Midwest or Pacific Northwest location. **L-469**

MISCELLANEOUS

Public Health Nurse. B.S. in nursing, William and Mary College, age 53, seeks position as coordinator of public health nursing, educational director, or director student nurse public health program. Preference as to location Middle Atlantic States. **M-452**

NEWS FROM THE FIELD

New School of Public Health Building, University of Michigan

UNIVERSITY OF MICHIGAN SCHOOL OF PUBLIC HEALTH

The new building housing the School of Public Health, University of Michigan, Ann Arbor, is now in use for students. The quarters assigned to the several departments were occupied during the late summer and early fall months. According to the Michigan Alumnus, this building was built and equipped at a cost of three-quarters of a million dollars as a gift to the University of Michigan from the W. K. Kellogg Foundation and the Rockefeller Foundation. An additional grant was made from the National Foundation for Infantile Paralysis in view of the large amount of work expected to be done by the school in the study of this disease.

The Regents of the University of Michigan created the School of Public Health in 1941 from the Division of

Hygiene and Public Health which has been organized as such since 1921. Henry F. Vaughan, Dr.P.H., son of the late Dean Victor C. Vaughan of the Medical School, was named the first Dean of the new school. The faculty has been assembled from a nucleus of the teaching staff of the former Division.

"Research holds a coördinate position with teaching in the operation of Michigan's School of Public Health. This is revealed most persuasively in the floor plans. Whole wings are given over to the needs of the researchers and their staffs. The presence of animal rooms reveals to the visitor forcibly that in this building scientists are studying and experimenting."

Among the features of the school are continuation study courses, including a plan for continued education through

short courses for individuals employed in public health services, physicians and dentists in private practice, and other professional groups with a major interest in health science services. Courses are also offered to milk plant operators, hotel and restaurant managers concerned with food handling, well drillers, plumbers, and the various occupations connected with industrial activity. Other courses are provided for public officials whose responsibilities involve health problems, such as county supervisors, health board members, school officials, public works and service officials, probate judges, etc. A recent course included study in industrial hygiene for plant safety personnel.

A feature of the fall program included a 4 day conference of teachers of public health from all parts of North and South America which was called for the purpose of working out exchange relationships between the countries and between universities specializing in this field.

SUPPLY OF PENICILLIN

Because of numerous requests received by the Army for penicillin, Surgeon General Normal T. Kirk of the Army Medical Department has explained that the War Department "at no time has either controlled penicillin or received the entire output." The Army's position with regard to penicillin supply is exactly the same as that of the Navy, U. S. Public Health Service, and the Office of Scientific Research and Development, each of which receives a monthly allocation of penicillin from the War Production Board. General Kirk also explained that the penicillin allocated to the Army Medical Department is intended for the treatment of military personnel and "none of it can be reallocated or released to civilians."

Penicillin is a new drug which is being tried out in Army, Navy, and

civilian hospitals in the treatment of serious types of infections which will not respond to sulfa drugs. The supply of penicillin is limited and distribution is controlled by WPB. This month, according to WPB, the Army will receive 56 per cent of the total supply, the Navy 18 per cent, U. S. Public Health Service (for the treatment of Coast Guard and Merchant Marine personnel) 2 per cent, the Office of Scientific Research (for civilians) approximately 15 per cent, and the remainder to the scientific staffs of drug companies for their own research.

Though production of the drug is steadily increasing, at present none of the agencies, including the military, receives as much as it needs. Its distribution among military and naval personnel is determined by the Army, Navy, and the U. S. Public Health Service. Distribution of the part allocated to civilians is for clinical research and its assignment is determined by a committee headed by Dr. Chester S. Keefer, Evans Memorial Hospital, Boston. Since the amount of penicillin requested by civilians greatly exceeds the available supply, it has been determined by the Office of Scientific Research and Development that civilian requests must be made through their doctors who should communicate with Dr. Keefer by telephone, telegram, or personal letter giving complete details of the case so that he may have an adequate basis for his decision.

NATIONAL SOCIAL HYGIENE DAY, FEBRUARY 2, 1944

The American Social Hygiene Association, New York, N. Y., has announced that it will again sponsor National Social Hygiene Day as an occasion in many communities for intensifying the year-round campaign against venereal diseases and conditions favorable to their spread. Dr. Walter C. Clarke, Executive Director of the As-

sociation, has announced that united community action against venereal disease is the theme of the plans made for February 2. Interested individuals and groups may obtain full details by writing to the American Social Hygiene Association, 1790 Broadway, New York 19, N. Y.

PUBLIC HEALTH FEATURES OF THE UNITED NATIONS RELIEF AND REHABILITATION ADMINISTRATION

The public press has carried recently extensive accounts of the meetings of the Council of the United Nations Relief and Rehabilitation Administration in Washington and Atlantic City. A summary of some of the features especially relating to health is presented herewith. The *Journal* is grateful to Selskar M. Gunn who was in attendance at the sessions of the Council and who has indicated the areas of special interest to health workers.

The Sub-Committee on Policies with Respect to Medical Care has been under the chairmanship of Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service. This sub-committee belongs to Committee IV, the Committee on Relief and Rehabilitation Policies, of which the Chairman is Dr. Tingfu F. Tsiang of China.

The terms of reference of this committee are set forth in the UNRRA agreement as follows:

" . . . that immediately upon the liberation of any area by the armed forces of the United Nations or as a consequence of the retreat of the enemy, the population thereof shall receive aid and relief from their sufferings, food, clothing and shelter, aid in the prevention of pestilence and in the recovery of the health of the people, and that preparation and arrangements shall be made for the return of prisoners and exiles to their homes and for assistance in the resumption of urgently needed agricultural and industrial production and the restoration of essential services."

The significant features of the ap-

proved resolution relating to health and medical care include the following:

1. A recommendation that governments provide for the notification of diseases likely to become epidemic and for uniformity in quarantine regulations and other measures of prevention.

2. It is recommended that governments, when requested by the UNRRA administration, offer facilities in making available suitable personnel for a health organization, including the temporary loan of technical experts and the services of scientific institutions.

3. It is recommended that there be the closest collaboration between the UNRRA administration and the Allied military authorities with reference to the notification of infectious diseases and to the orderly transfer to the administration of epidemic control and other public health measures put into operation by the military authorities.

4. It is recommended that governments, when requested by the UNRRA administration, facilitate in every way the assignment of their nationals from the occupied countries for technical training, especially in the newer aspects of medical and sanitary sciences.

Scope of the Health Work of UNRRA

1. Health work will necessarily constitute one of the primary and fundamental responsibilities of UNRRA.

2. This program is to consist chiefly of the provision of assistance to governments in the rapid reestablishment of their health services generally, preventive and curative. These services include not only disease control and relief from malnutrition but the reestablishment of medical services, hospitals, dispensaries, sanatoria, health centers, laboratories, environmental sanitation, maternity and child welfare services, control of endemic diseases, particularly tuberculosis and venereal diseases, and other essentials for health. UNRRA should be prepared to give assistance with equipment and supplies, personnel, expert advice, facilities for technical training and the collection and dissemination of information bearing on the above problems.

3. One of the aims of UNRRA should be to equalize opportunity for the restoration of health in the various countries. This will involve a sharing of responsibilities and equitable distribution of goods and other assistance in proportion to need and in accordance with a coordinated plan.

4. In view of the obvious importance of dealing rapidly with epidemics, it is essential

that the health organization have at its immediate disposal trained personnel and material.

5. The health organization may be called upon to provide for the loan of experts to various countries, particularly in cases where diseases have been introduced for the first time as a result of the war and with the control of which neither the national health authority nor the local practitioners are familiar.

6. The medical aspects of nutrition will constitute one of the chief preoccupations of the health organization which will be urgently concerned with the provision of nutritional standards adequate for the maintenance of health in the territories in which it operates.

7. The health organization will play an extremely important part in the health supervision and control of returning displaced persons.

8. The special health needs of children and expectant and nursing mothers must be given early recognition by the health organization. The health organization may also be called upon to assist in dealing with the conditions of anxiety, fear and emotional disturbance which will have arisen in peculiarly great frequency among the children and youths of occupied territory.

9. A constant objective of the health program should be to demonstrate the effectiveness and need of international collaboration in public health. In so doing it will facilitate the later development of a permanent world-wide health organization.

10. Whenever possible the national and local health services should be the channels through which the health work of relief and rehabilitation operations are carried out and it should be a constant objective to assist in strengthening these services.

11. A special section in the health organization for epidemiological control is suggested in order to promote collaboration between member governments in the control of epidemic diseases.

12. Coöperation with existing governmental health agencies should be fostered.

13. The wide experience and good will of the non-governmental health agencies should be utilized to the utmost as it is clear that the full participation of all such agencies may well be needed. In accordance with the terms of the agreement, plans and policies should be developed whereby the resources of such organizations may be used effectively in those health aspects of relief and rehabilitation to which they have special relationship.

14. The reestablishment of health being one of the principal objects of relief work,

it is essential that the status of the health organization should be commensurate with its importance in the work of the whole administration. It is a recognized principle of administration that all work of a technical character be carried out under technical direction. In view of the fact that almost every aspect of the work of UNRRA will necessarily have health implications (programming, supplies, personnel, training, coöperation with governments, field operations, etc.), the director of health must be afforded a position in the administration which will enable him under the authority of the Director General to develop suitable policies and to exercise proper technical direction over all health aspects of the work of UNRRA.

15. The health organization should consist of a director of health and a technical and administrative staff, a standing technical committee on health which would be advisory to the Council, to the Central Committee, and to the Medical Director, and the necessary regional organization. Experience has shown that a considerable degree of decentralization is desirable in health administration, so that strong regional organizations will be needed in areas such as Europe and the Far East.

16. The director of health should be accorded a position in the administration which will enable him under the authority of the Director General to direct suitable policies and to exercise proper technical direction over all health aspects of UNRRA. He will be directly concerned in all major policy and administrative decisions in which health, medical or nutrition problems are involved. It follows that the status and success of UNRRA from the health point of view depend upon obtaining the services of a director of health of the highest possible professional standing, whose previous work is such as to command the respect of those qualified to judge, both from a technical and administrative point of view. A regional health director should be appointed to each regional organization with a position relatively similar to that provided for the director of health.

17. The greatest care will be required in selecting health personnel for field work in the various countries. Technical competence is fundamental, but almost equally important is the ability to work in a team with others of different nationality, as the staff will necessarily include health personnel from a number of countries. This qualification is of primary importance for members of the staff required to work away from headquarters, for they must be able to understand the out-

look of the people among whom they are called upon to work. In comparison with this qualification, a knowledge of languages, though a valuable asset, is of secondary importance.

18. It is impossible to anticipate what types of individual or special missions may be required. Requests may come for highly technical assistance in almost any branch of medical or sanitary science, particularly in view of the isolation of many of the experts of these nations during the years of war. UNRRA should collect information regarding individual experts and expert teams which might be made available for service in the field should the occasion arise.

19. A standing technical committee on health should be appointed, as provided for in the agreement. The members should be limited to between 9 and 15. It is urged that members of the committee should have as alternates persons technically capable of aiding in the deliberations of the committee.

20. In view of the highly technical character of the health work of UNRRA it will be essential to have authority to appoint expert commissions. The members of these commissions should be nominated as individuals solely on the ground of their special knowledge of the subject concerned. As members of expert commissions speak as individuals only, there is no necessity to make any such commission even approximately representative of a number of countries.

21. Expert commissions on nutrition will be required in view of the wide differences obtaining in the food habits and nutritional status between various parts of the world. The director of health should be able to summon either centrally or regionally conferences of directors of national public health services whenever practicable and desirable.

22. Among the tasks calling for immediate action is the obtaining of medical literature dealing with the progress of medicine and hygiene during the years of war for the liberated countries.

23. Even though it may not be possible for UNRRA to meet all the relief and rehabilitation needs of the populations affected by the war, nevertheless by approaching the tasks through the wise use of the technical resources of the United Nations, mobilized and engaged in the same spirit of coöperation as they are now devoting to the prosecution of the war, it should be possible, in the public health sphere, to attain comparable success in the war against disease and for the restoration of health.

The personnel of the Sub-Committee

on Policy with Respect to Health and Medical Care at the time of the conference was as follows: *Chairman*, Thomas Parran, M.D., United States; Mr. Sitsen, Netherlands, alternates Dr. W. M. Bonne and Dr. J. A. F. van den Belt; Dr. Galtung Hansen, Norway, alternate Dr. Nicolaysen; Ricardo A. Morales, Panama, alternate Narciso E. Garay; Dr. Celso R. Velazquez, Paraguay, alternate Dr. Paris E. Menendez; Juan Chayez, Peru, alternate Julio Balbuena; J. M. Elizalde, Philippines, alternate Dr. A. B. Rotor; Prof. B. Nowakowski, Poland, alternates Dr. Artur Lejwa and Dr. Alexander Rytel; A. T. Brennan, Union of South Africa, alternate R. Webster; Dr. V. Lebedenko, Union of Soviet Socialist Republics; Dr. Melville Mackenzie, United Kingdom; Dr. Leo Rabinovitch, Yugoslavia, alternate George Radin. Representing the Director General, Frank G. Boudreau, M.D., alternate Selskar M. Gunn.

LABORATORY EQUIPMENT CONTROL EASED

Control over the distribution of laboratory equipment has been eased by WPB through issuance of Order L-144 as amended. Authorization of purchase orders for the following items, designated "List A," is still mandatory, except in the case of distributors' purchase orders; Analytical balances (sensitivity 1/5 mg. or more sensitive); Calorimeters; Centrifuges; Hydrogen ion meters (electrometric); Metalloscopes; Microscopes (except Brinnel and Tool Makers); Microtomes; Potentiometers, Wheatstone Bridges and Resistance Boxes; Refractometers; Spectrographs, spectrosopes, spectrometers and spectrophotometers; Vacuum pumps (1 micron or higher vacuum).

No authorization is now required for items not on list A, as the amended order removes former additional restrictions on deliveries. These prohibited the filling of purchase orders for items

having a value of \$50 or more, for quantities of the same item aggregating \$50 or more, or for quantities of items aggregating \$200 or more, except upon specific WPB authorization, or for delivery to the Army or Navy, serial-numbered laboratories, and distributors.

The amended order also:

1. Puts distributors located in Canada on the same basis as those located in the United States, its territories and possessions.

2. Revises List A by removing several items formerly included and by using specific names of instruments in all cases.

3. Makes clear that List A does not include secondhand equipment or parts for maintenance and repair of existing equipment, and that the list applies only to items designed primarily for use in laboratories.

SEATTLE PLANS POST-WAR HEALTH BUILDING

Ragnar T. Westman, M.D., Acting Commissioner of Health of Seattle, Wash., has announced that the city is making post-war building plans for the erection of a new public health building to house all divisions of the Department of Health and Sanitation and that it is first on the list of proposals.

Dr. Westman would be glad to correspond with health officers of other cities who are making similar plans for the post-war period.

UNIFORM ACT ON PUBLIC HEALTH UNITS

The Conference of Commissioners on Uniform State Laws has authorized the Chairman of its Public Law Acts Section to draft a uniform act on Public Health Units for the guidance of state legislatures drafting public health legislation. At the present time many states do not have legislation permitting, and indeed some have legislation prohibiting, city-county or multi-county full-time local health units. The model law being drafted by the Conference will be designed to facilitate state action on a substantially uniform basis in organizing units of local health service suitable in size, area, and other charac-

teristics both to justify and support an adequate and well rounded professional supervisory and field staff. The Conference, in drafting this law, is acting upon the request of the APHA Subcommittee on Local Health Units. The Chairman of the Public Law Acts Section who is drafting this legislation is Robert K. Bell, an attorney of Ocean City, N. J.

AMERICAN SOCIETY FOR THE CONTROL OF CANCER APPOINTS EXECUTIVE

J. Louis Neff of East Williston, Long Island, N. Y., has been appointed Executive Director of the American Society for the Control of Cancer, New York, effective January 1. Since 1923 Mr. Neff has been Executive Secretary of the Nassau County, N. Y., Medical Society and Secretary of the Nassau County Cancer Committee since 1928. Mr. Neff is a member of the Section Council of the Public Health Education Section, and a Fellow of the A.P.H.A.

MICHIGAN PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

At the Annual Business Meeting of the Michigan Public Health Association held in Grand Rapids on November 4, the following officers were elected:

President—John M. Hepler, C.E., Lansing
President-Elect—Nathan Sinai, Dr.P.H., Ann Arbor
Vice-President—Hugh Robins, M.D., Marshall
Secy. Treasurer—Marjorie Delavan, Lansing
Representative on Governing Council of A.P.H.A.—Emilie G. Sargent, R.N., Detroit
Directors—Joseph G. Molner, M.D., Detroit, 1946 (At Large); Percy M. Phelps, Grand Rapids, 1946 (Representing the Michigan Association of Sanitarians)

This was the 23rd Annual Public Health Conference held by the Michigan Public Health Association and 605 persons were registered from all sections of the state. The emphasis was on group discussion of urgent problems. A half-day meeting of the Michi-

gan School Health Association followed the adjournment of the public health conference.

PAN AMERICAN HEALTH DAY ESSAY CONTEST

Dr. Hugh S. Cumming, the Director of the Pan American Sanitary Bureau, Washington, has recently announced, in connection with Pan American Health Day, that there would be held an essay contest for high school students to encourage thought about the value of health and of international coöperation in health matters. The prizes, offered by the Lily Tulip Cup Corporation, will consist of \$75, \$50, and \$25 War Bonds. The theme of the essay is to be "What My Country Has Contributed to International Health Coöperation or Knowledge in the Field of Water, Food and Beverage Sanitation." The essays, which are limited to 2,000 words, must be received by the Pan American Sanitary Bureau not later than May 31, 1944, and the contest is open to students in the 11th and 12th grades of high school. Further information can be obtained from the Pan American Sanitary Bureau, Washington 6, D. C.

CENTER FOR THE DEVELOPMENT OF PHYSICAL MEDICINE

The National Foundation for Infantile Paralysis, Inc., has announced a grant to the Graduate School of Medicine of the University of Pennsylvania, Philadelphia, totaling \$150,000 for a 5 year period for the establishment of what is said to be "the first center for the scientific study and development of physical medicine as a branch of medical practice."

According to Basil O'Connor, President of the Foundation, this represents a continuation of the interest which the Foundation has had in the part which physical medicine can play in the treatment of infantile paralysis. More than \$350,000 has been spent during

the past 6 years to educate and train physical therapy technicians. An additional \$364,000 has been granted for the study of problems in physiology and medicine bearing on physical therapy. The Departments of Anatomy, Physiology, Pathology, and other basic sciences of the University of Pennsylvania will coöperate in this program which will be under the general direction of Dr. Robin C. Buerki, Dean of the Graduate School of Medicine.

SOUTH CAROLINA PUBLIC HEALTH ASSOCIATION

At a recent meeting, the South Carolina Public Health Association elected the following officers to serve for the coming year:

President—G. S. T. Peebles, M.D., Columbia
1st Vice-President—Lavinia Baskin, R.N.,
Moncks Corner
2nd Vice-President—C. G. Leonard, Spartan-
burg
Secretary-Treasurer—Mrs. Frank George,
R.N., Columbia

DR. J. H. KELLOGG DIES, A.P.H.A.'S OLDEST MEMBER

John Harvey Kellogg, M.D., of Battle Creek, Mich., died on December 14 after a brief illness, at the age of 91. For many years Dr. Kellogg was Director of the Battle Creek Sanitarium where he developed many routines for what he called "biologic living."

Dr. Kellogg joined the American Public Health Association in 1878 and recently completed 65 years of continuous membership, the longest on record. He is believed also to have been the oldest member of the Association. A certificate for long membership in the American Public Health Association was given to Dr. Kellogg in 1936 when the Association met in New Orleans.

Active up to the last, Dr. Kellogg maintained his interest in diet and in efforts to avoid what he believed to be a serious racial deterioration as the result of unhygienic living.

TEXAS WATER WORKS AND SEWERAGE SHORT SCHOOL

The 26th Annual Texas Water Works and Sewerage Short School will be held at Texas A. & M. College, College Station, Tex., January 31–February 2.

The three full days will be devoted to discussions on such important topics as recent developments in priorities, the function of the Office of War Utilities, use of idle equipment, man power problems, post-war planning, the U. S. Public Health Service Standards for drinking water, water supply security, in-service training of water and sewage plant operators, the latest developments in the relation of poliomyelitis transmission and sewage, as well as the relation of Army and Navy standards to the operation of municipal utilities, and new developments in the various fields.

KANSAS CITY-WYANDOTTE COUNTY PROGRAM

Wyandotte County recently consolidated with the City of Kansas City, Kan., in a joint health program under the Direction of William H. Pickett, M.D., Surg. (R), U. S. Public Health Service. The consolidated health unit also has a Health Center building now housing the entire department. The Health Center was provided through a Lanham Act project under the Federal Works Agency. Building and remodeling, as well as much new equipment, were provided by the project.

PERSONALS

Central States

ERNEST J. BECKNER, M.D.,† of Pratt, Kans., has been appointed Health Officer of Butler County, succeeding SAMUEL N. MALLISON, M.D.†

VERNON P. CROCKETT, Assistant Engineer, U. S. Public Health Service (R), has been assigned to the Kansas City (Kan.)-Wyandotte County

Health Department to have charge of Public Health Engineering.

LUNSFORD D. FRICKS, M.D., D.P.H.,* has resigned as Health Officer of Helena and Lewis and Clark County, Mont., because of poor health. His resignation was effective August 31. E. K. MUSSON, M.D., M.P.H.,* is on leave from his position as Chief Medical Officer of the Chicago Health Department, Chicago, Ill., and has been commissioned Senior Surgeon in the U. S. Public Health Service Reserve and assigned to the Chief Medical Officer, Office of Foreign Relief and Rehabilitation Operations. Dr. Musson has been ordered to the School of Military Government, Charlottesville, Va., for three months' training, after which he presumably will be assigned abroad.

Eastern States

LEON A. BEARDSLEY, M.D., of Ithaca, N. Y., has been appointed Health Officer of Caldwell, Lyon and Crittenden Counties, Ky., effective August 24.

LEVERETT D. BRISTOL, M.D., DR.P.H.,* formerly Health Director of the American Telephone and Telegraph Company, New York, N. Y., has been appointed Executive Director of the Hospital Council of Greater New York.

LT. BERNARD D. DAITZ, SN.C., A.U.S.,† is now serving with the Allied Commission, formerly AMGOT. His address is 2675 Regiment, A.P.O. 512, New York, N. Y.

MAJOR GENERAL JAMES CARRE MAGEE, Medical Corps, United States Army, retired, has been named Executive Officer of the information service of the Division of Medical Sciences of the National Research Council. This service has been established by the

* Fellow A.P.H.A.

† Member A.P.H.A.

Council under the recent grant of the Johnson & Johnson Research Foundation of New Brunswick, N. J.

MARION I. MURPHY, R.N., who for several years has been Director of Nursing in the Cattaraugus County Department of Health, Olean, N. Y., resigned, effective November 25, to accept a position as Assistant Director in the Bureau of Public Health Nursing in the Michigan State Department of Health, Lansing.

MARGUERITE PRINDIVILLE, R.N., who has been Director of the Eastchester Public Health Nursing Organization, Tuckahoe, N. Y., has resigned to accept the position as Director of the Seattle Visiting Nurse Service, Seattle, Wash. Miss Prindiville will participate in an amalgamated program with the Seattle Department of Health and Sanitation. It is expected that she will later become Director of the new Division of Public Health Nursing in the Department of Health.

Southern States

GUY B. ANDERSON, M.D.,† of Ellicott City, Md., has resigned as Health Officer of Howard County.

EDWARD M. BARNES, M.D., formerly of Tampa, Fla., is the Director of Health of the new Health Department established in Galveston County, with headquarters in LaMarque, Tex.

E. R. COFFEY, M.D.,* of the staff of the U. S. Public Health Service, who for some years has served as Assistant Surgeon General in charge of the Division of Sanitary Reports and Statistics, Washington, has been appointed Director of District No. 1 for the Service with headquarters in New York. Dr. Coffey was formerly State Health Officer of Washington.

NAOMI DEUTSCH, R.N.,* formerly in charge of the Nursing Service of the U. S. Children's Bureau, has arrived in Managua, Nicaragua, to give a series of lectures and demonstrations in connection with poliomyelitis, according to the press on December 1.

CHARLES C. HEDGES, M.D.,* who since May 1, 1939, has been Health Officer of Savannah and Chatham County, Ga., has resigned to become Medical Director of the Vallejo Community Hospital, Vallejo, Calif. Dr. Hedges has been succeeded by CLAIR A. HENDERSON, M.D., who has been Commissioner of Health of Augusta, Ga., and Richmond County.

ELLSWORTH H. JOIN, M.D., of Brownsville, Ky., has been appointed in charge of tri-county health unit of Meade, Breckinridge and Hancock Counties, with offices in Hardinsburg.

HENRY R. O'BRIEN, M.D., M.P.H.,* is on active duty as Senior Surgeon (R) in the U. S. Public Health Service, assigned to the Office of Foreign Relief and Rehabilitation Operations, and detailed to the School of Military Government at Charlottesville, Va. Dr. O'Brien has resigned as chief of the Division of Local Health Administration in the Connecticut State Department of Health, Hartford.

Western States

BEVERLY C. BOOTH † has resigned as Sanitarian in the El Paso County Health Unit, Colorado Springs, Colo., and has accepted a position as Public Health Engineer in the Division of Sanitary Engineering, South Dakota State Board of Health, Pierre. GLEN J. HOPKINS † is the Director of the Division.

FRED T. FOARD, M.D.,* Surgeon, U. S. Public Health Service, has been

Health IS Social Security*

HOMER FOLKS, LL.D., F.A.P.H.A.

Secretary, State Charities Aid Association, New York, N. Y.

As each of us develops from the complete dependency of infancy to the independence of adult years, we gradually acquire an earning capacity, and we likewise acquire continuing responsibilities—to support ourselves, to support or care for a family, to be useful citizens, good members of a community. These two factors of income and of obligation are not tied together chronologically. The income may diminish, or disappear, but the obligations continue.

Social security, in a broad sense, is an effort to tie together chronologically the factors of income and of obligations; so that if income is cut down or disappears, by reason of illness, accident, death, or unemployment, the obligations can still be met. That this is a desirable objective, both from point of view of the individual and of the community, is obvious. The question is by what methods it can be most successfully attained. Few of us, if any, reach the later years of adult life without facing, at least once, and for some of us repeatedly, the possibility of

greatly reduced income, without reduced obligations. Social security, in that sense, is for each of us a matter of personal interest. But how can it be attained?

There are many kinds of interference with income. Obviously, we must consider each such cause separately. The simplest approach to security, or at least the approach which is now under widespread consideration, is that of replacing the normal income during its diminution or absence, by payments from a fund which has been accumulated piecemeal by small weekly payments by all potential recipients and by their employers. This is a form of social security; and, in essence, it is social insurance. However, another possibility demands prior consideration as being inherently more desirable, when practicable; the alternative of preventing the interference with income. It scarcely requires argument that prevention is better than cure, cheaper, tremendously more acceptable.

Under reasonably normal conditions, i.e., in the absence of a depression and, therefore, in the absence of widespread unemployment, the major interferences with income arise from illness and premature death. Can illness be pre-

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

vented? Can premature death be prevented? To ask these questions at such a meeting as this is carrying a large supply of coal to Newcastle. Through the efforts of the authorities, agencies, and individuals in attendance or represented here, untold hundreds of thousands of illnesses have been prevented, and untold thousands of premature deaths have been averted. It is as simple as addition or multiplication that these public health authorities, by preventing illness, have prevented interference with income in hundreds of thousands of cases. In this fashion, public health has been, during the past hundred years, a dynamic factor in the conservation of family income, and thus has made an enormous contribution to social security. In fact, health, a necessary condition of earning, is, *ipso facto*, a form of social security.

Furthermore, it is social security of the most acceptable and useful type. The continuing receipt of income, after all, is not the only factor in social security. The situation of a wife whose husband is living, active, earning, and meeting his family responsibilities, is tremendously different from that of a widow who receives a check once a month—much less than her husband formerly earned—from an old age and survivors insurance fund, but at whose table, three times a day, the place of the head of the family is vacant. That difference is precisely the measure of the difference between security arising from public health (when that is possible) and security arising from social insurance.

We need now to ask several questions as to public health social security. How large a factor has it been up to now? Has it been as large a factor as it should have been? If not, what has interfered with its desirable growth? How can we remove those interferences from now on? By what major channels can public health security attain its

maximum effectiveness, and thereby reduce the volume of need for social insurance security?

This audience, more than any other group, can quickly recall the tremendous decrease in the volume of sickness and death brought about, in some instances wholly, in other instances largely, and in still other instances in lesser degree, by public health agencies and practices. How different would be the circumstances of our lives had there been no vaccination against smallpox, no effective prevention of typhoid fever, if yellow fever were as frequent in this country as it was a century ago; if tuberculosis were at its volume of even forty years ago; if there had been no preventive campaign against diphtheria; if the dangers of childbirth had not been diminished to such a substantial degree during the past decade. We need not bring into action the processes of statistical calculation to realize that through such efforts the incomes of countless individuals have been preserved, and the lives of fathers and mothers conserved for their families, to an extent which, in its full volume and significance, may be beyond the imagination even of the group here present.

Although public health has done much, we must ask ourselves, could it have done more? Could we have prevented more speedily and more generally the diseases just mentioned and others, as to which scientific preventive procedures have become practicable? We must admit, of course, that though we have labored diligently, we have accomplished only a minor fraction of what it has been scientifically possible to accomplish. There has continued to be a great volume of poverty, distress, breaking up of families, because of illnesses and deaths, which it was scientifically possible to prevent. What are some of the reasons why our success has been only partial? We probably would not have many differences of

opinion on this subject. I would recall them in about the following terms:

1. We have not, as a rule, presented our opportunities for disease prevention to the public and to the various governmental units with much imagination or with much confidence or courage. We have been troubled by our inability to guarantee one hundred per cent return on the money we asked for. We have been embarrassed because we could not always "prove" in advance just what we could accomplish. We have therefore understated our case.

2. As a result, we have received even smaller grants of funds from fiscal authorities than we asked for. Our plans, already much too limited when proposed by us, have been greatly reduced, and the specific grants have been inadequate for the purposes for which they were made.

3. We have accepted these limitations too readily, without continuing protests and promotional efforts aimed to inform the entire community. We have become almost contented far too easily with doing small things or minor fractions of several things without keeping in mind our total opportunities.

4. As a result, we have not even planned total war against preventable diseases. We have planned the initial approaches, the early stages, an experiment or a demonstration, but have not followed up the experiment or the demonstration as to its possibilities as applied to the total need.

5. Health activities have been much too localized in small units of government, towns, and villages, with small resources and with no qualified or trained personnel. If you will read, *England's Road to Social Security, 1349-1942*, you will be impressed, as reviewers of the book have been, with the fact that for this 600 years the trend has been steadily away from "localism" toward larger and larger governmental units of administration

and of finance, until a large part of these welfare operations is now on a nationally administered and nationally supported basis. During a much shorter time, and as yet to a minor degree, this trend is plainly visible in public health administration in this country. It is to my mind an inherent trend in any sound and effective development of public health, but it does not follow by any means that we will go the whole distance toward national operation or national support. We are very far from having achieved, as yet, that balance between local, state, and federal participation in finance and in administration which will secure for each person in the country even a reasonable degree of health protection, and therefore of health social security.

6. Partisan politics, especially in small units of government, have often paralyzed the activities of health authorities, or have prevented the utilization of men who have even a slight understanding of public health possibilities.

7. It must be put into the record, too, because it is a fact, regrettable though it is, that medical organizations, local, state, and federal, often with only a slight understanding of public health problems, have been bewildered and alarmed by governmental action in public health; have opposed plans that were not microscopic in volume; and have tried to insist upon administration by the small governmental units, which were more likely to be subject to their influence. This is not always the case, but it is the general picture.

This enumeration of some of the factors which have restrained the public health movement from accomplishing more nearly that great volume of health security for which there was adequate scientific basis, must not lead us to underestimate the striking results that have been achieved, nor above all to fail to make more adequate plans for

the future. The quickest way to conserve individual incomes and family resources, is by more and more and better and better public health. We may well consider for a few moments some of the steps which would help in achieving that larger development of public health which is easily within our grasp financially and administratively, and the failure to achieve which is a standing reproach to us as communities, states, and as a nation. Here are some of the things which it seems to me we must do. To a degree they are simply the reverse of the factors mentioned a few minutes ago as having restrained us heretofore.

1. Once and for all we must recover from the fallacy of picayune plans. We must no longer be afraid of adequate plans, plans which are as big as the evils which they aim to control. As a matter of fact, it is often easier to secure the adoption of a big plan than of a little one. A little plan, offered in face of a big need, suggests little officials to whom fiscal authorities do not need to pay much attention. We Americans are convinced that we are the most resourceful, energetic, dynamic, competent people now existing. I judge that we are; but this is not true as to our public health progress. Why should we be relatively (as compared with other functions) a backward people in this most strategic of social opportunities?

2. To make good in a big way in our plans for the prevention of disease and the postponement of death, we must keep the preventive objective clearly in mind; as Willkie said to Stalin, "We must keep our eye on the ball." Until we have gotten much farther along toward the complete control of tuberculosis, syphilis, gonorrhea, and other communicable and preventable diseases, we cannot, as health authorities, seek or take on the tremendous task of securing good medical care of all sorts for every-

body. That may come unsought, in some degree, in time, probably piecemeal, but we certainly are not ready for it now. Our health agencies have already hoisted their flags over large fields, some of which (possibly most of which) they occupy so thinly as to be most ineffective. To spread out over still wider areas, would mean being even less effective than we are now in many of our preventive efforts.

3. The antidote for partisan politics is *non-partisan* politics, i.e., to present an alluring program in simple words, to arouse public interest and wide public support for it, and thus to create a healthy climate in which political interference with health measures is definitely dangerous.

4. We must not be afraid of whatever degree of centralization the total situation may call for from time to time. In most instances, this would not mean the substitution of centralized action *in place of* a local one; it is much more often the development of effective methods of action in larger units, of doing what the smaller units have failed to accomplish or even to undertake. There are underlying, inherent, and to my mind, inescapable factors which lead step by step to the development of participation, either financially or operationally, by larger and larger units—by counties in addition to towns and villages, by the state in addition to cities and counties, by the federal government in addition to states. There is nothing undemocratic about this process. Small local units of government are in no true sense the "shrines" or "schools" of democracy. They are often, under present conditions, its most serious failures, least competent, most wasteful, most given to missing the ball and failing to get results. That plan is most truly democratic, as to the relation between the various areas of government, which works best as times and circumstances change.

5. The vocabulary of public health is rapidly increasing in volume, but there is one word which should not be found in any public health literature or law. That is the word "indigent." It is a sound and necessary word in public relief, but not in public health. Public health is concerned with the welfare of *all* members of the community. It is a public service for the benefit of all who need such service. It has no special interest in indigents or any other economic group as such. The considerations and methods for the control of disease are the same throughout the entire community. Public health activities in this respect must be on exactly the same basis as public education, its opportunities open to all, free to all, paid for out of the total community resources, and available to all with no "stigma" of charity or relief such as would deter many from seeking or utilizing it. As a matter of fact, there is no such "stigma" in the utilization of community services that are intended for all the people needing them. Schools, fire protection, police protection, parks, playgrounds, highways, all these are community enterprises, paid for from general taxation which, as it affects the standard of living and the cost of living, are shared by every person in the community, and every person is therefore entitled to avail himself of these services without feeling, and without it being a fact, that he is "getting something for nothing." He has been paying all along for the maintenance of these health services, and if and when he needs them, or the community needs them for its protection, he is getting something that he has been paying for all along and is now paying for.

6. The preparation of adequate plans for dealing with known health hazards has already been emphasized. It is equally important to keep these plans flexible, and from year to year to con-

sider what modifications have become desirable, or perhaps imperative, by reason of additions to our scientific knowledge. This is true in nearly every field of health activity. New discoveries are not like additional building blocks in the construction of a wall or a building—simply additional material of the same kind. New discoveries nearly always bring not only additional duties—they nearly always call for re-appraisal, rearrangement, oftentimes of a fundamental character. The new knowledge may raise doubts about some things taken for granted; it may confirm the validity of what had, up to that time, been a matter of probability.

A very notable instance in one of our long-standing health activities is in the field of tuberculosis. New knowledge as to the effective use of chest x-rays, and new methods greatly reducing the cost of large numbers of x-ray diagnoses put into our hands far more effective facilities than we have heretofore had for the elimination of tuberculosis. It is now practicable to think in terms of x-raying the entire population of various areas, beginning perhaps with areas in which tuberculosis rates are still high. We can get rather definite estimates as to the number of cases which will be discovered in the various stages of the disease. We can formulate tentative estimates as to the additional number of hospital beds that will be required, and as to the numbers for whom partial or complete rest at home may be adequate. We can also judge as to the frequency with which such x-ray examinations will need to be repeated in any given locality, in order to catch the most recent infections.

While this knowledge of more effective tuberculosis methods has been available for some years, little has been done in planning a thorough-going job in taking the complete measure of tuberculosis in given areas, and of providing

for such areas all the facilities required for making the fullest use of the result of the diagnostic examinations.

The changing types of curative treatment for syphilis within much shorter periods, as well as for gonorrhea, present the possibility of revolutionary gains in the control of those diseases, and so all along the line. We have to learn to be comfortable in the presence of possibilities of change, without notice, so to speak, in the scientific bases of all our health activities. Also, of course, we have to keep an eye out at all times for new knowledge bringing other diseases into the preventable category. Not all of these will require the aid of health authorities, but many of them will.

In all that has been said as to the importance of the promotion of health as a very direct and dynamic form of social security, there is no intention of underestimating in the slightest degree the importance of the various forms of social insurance and social security as related to those interferences with income as to which the causes are not pre-

ventable by any practical means now within our knowledge and capacity. On the contrary, the situation is in no degree that of exclusively either this or that. It is a question of both. It is highly significant that in the original Federal Social Security Bill there was included a provision authorizing an additional appropriation of \$10,000,000 a year to the U. S. Public Health Service. This authorization was subsequently raised, and I believe now the ceiling has been removed from such appropriations. The fact that this was included in social security legislation is a fine recognition by Congress of the fact that the promotion of health actually is the promotion of social security. There should be the completest understanding and the fullest coöperation, between the agencies at the various levels of government dealing with the various forms of social security, each of which, far from interference, actually does promote and strengthen the other types of security.

Present Status of Health Insurance in the United States*

NATHAN SINAI, DR.P.H., F.A.P.H.A.

Professor of Public Health, University of Michigan, Ann Arbor, Mich.

TO describe the present status of health insurance in the United States is like trying to specify the position of a speeding train. By the time the words have been uttered the status they portray has become a matter of history—health insurance has moved forward.

It has been said with some scorn that the demand for health insurance trickles from "little groups of serious thinkers." The statement implies that health insurance is only a passing agitation and, to explain it, various causes are chosen and stressed. Ten years ago the agitation was due, assertedly, to the depression; five years ago, to the exhilaration of a rising prosperity; today, to an approaching national political campaign; tomorrow, it will be due, no doubt, to the natural unrest that usually follows a war. One or another of these phenomena is always present as a comforting refuge for those who would dodge the test that differentiates a social movement from a passing fad. Yet, the test is not too complex.

In a social movement the events that occur generate new events and each one exhibits a gain in strength and in force. In a passing fad most of the power is expended in the initial efforts; such subsequent events as occur exhibit the signs of diminishing power and

force, the signs of progressive weakness. The test takes time, but time has passed and the experience of ten years is now a part of the record. The evidence of the decade firmly establishes health insurance as one of the more visible signals of a dynamic social movement, a movement that involves all of the health professions, that embraces government, labor, and industry, that excites positive public support and even more positive individual action. Ten years ago health insurance was an issue; today, with all of its imperfections, it assumes the status of an institution.

These are generalizations; now for certain particulars.

As a part of a long series of events, each occurring as though it had fretfully awaited its moment, one might mention the extensive and intensive studies of the costs of illness, the distribution of the health services and the needs of the population. One might mention, also, the innumerable national and state conferences that have involved more and more organizations and greater and greater numbers of people. And one should note, appearing in the professional publications, a heavier and heavier sprinkling of items and articles on the subject of economics. All these, however, might be interpreted as evidence only of a philosophical preoccupation; as evidence, perhaps, of a statistical and verbal interest in the economic problems of the health services. But much more has happened.

First, the hospitals decided to com-

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

bine action with discussion and in 1932 began to open their doors and their services to people who had expressed their support of health insurance in a manner that admits of little argument. They had bought and paid for it and they have continued to buy and pay for it. Today 32 states and the District of Columbia have adopted enabling legislation to permit the organization of non-profit hospital insurance plans, and the American Hospital Association, through its Hospital Service Plan Commission, has approved 74 Blue Cross plans that in some instances cover whole states; in others, local areas. And today the approved plans have a subscriber membership that numbers approximately 13 million people. Add to the 13 millions an estimate of those who have purchased protection from mutual and other insurance companies, and the number exceeds 17 millions. If this be a measurement of the total of little groups of serious thinkers in the United States the intellectual future of the country is assured!

The medical plans started later and in too many instances as defenses against that mysterious force called "the government." Thus far, 13 states have adopted enabling legislation for medical plans comparable to that governing non-profit hospital insurance. And here, too, there is evidence of favorable public response. As a rule, the medical plans offered to the public are limited in their scope of service, the usual type of contract providing for surgical and obstetrical care in hospitals. Because there has been no consistent attempt, such as that for the hospital plans, to organize collection and to centralize experience and data, the number of people covered, one million, is a rough approximation. And the number of non-profit medical plans in the country is estimated at thirty-three.

As a third type there are the literally hundreds of industrial health insurance plans, many in existence for decades, whose benefits are open to people connected with specific industries or plants. In some instances, where a town or city draws its support from a single industry, virtually the whole population is included. In the industrial plans there may be found all of the variations that occur in health insurance, from the most comprehensive services to the most limited; from costs that are fully paid by employers to costs that fall wholly upon the employees; from services provided by groups of salaried physicians to services from private practitioners on a fee basis. And, again, the estimated number of people involved, 1½ millions, is a rough estimate.

Though these are the three main types of voluntary plans operating in the country, there are others such as the coöperative plans and those where medical groups offer their services to the public on a basis of prepayment. Nor is this all. The principle of health insurance has spread to the field of public medical service. Even though all or a portion of the costs of health services are borne by public funds, the allotments are made in terms of specified amounts per person or family per month or year. A notable example of health insurance in public medical service is to be seen in the arrangements and contracts of the Farm Security Administration for health services to selected families. As another example, the State of Washington has adopted a program of health insurance that provides complete health services—medical, dental, hospital, nursing, pharmaceutical and appliances to correct vision and hearing defects—for the "senior citizens" of that state, the 62,000 recipients of old age assistance. These are but two of the many state and local instances of health insurance applied to public medical services.

The status of health insurance now presents itself as an ocean-to-ocean panorama of intensive action that involves some 20 millions of people and excites the interest and the imaginations of other millions. Therefore, those who would speak of health insurance as though it were a matter that might call for consideration at some unstated future time demonstrate only one thing—an unwillingness to examine current events that indicate the widening scope of the movement toward more health services for more people.

What has all this to do with public health? Is this a subject that should interest public health workers only in their conventions or in their periods of recreational reading? The answer is an emphatic “NO” because any device or method that brings more health services to more people *is* public health. Yet, too generally speaking, public health workers have maintained a negative attitude toward what is happening in the nation, their states and, even worse, their local areas. To be sure, health insurance is emerging from a background of controversy and as long as it contains controversial elements there are some who prefer the unsatisfactory certainties of the present to the stimulating perplexities of the future. Others lean heavily upon some theoretical crutch of precedent to justify the avoidance of any activity outside of an established pattern of work. Yet such an interpretation of precedent collapses when one reads the early reports of Chadwick, Simon, Smith, and Chapin—those reports that stressed economic factors, that emphasized social problems, and that gave birth and vigorous life to public health itself.

Complete consistency is a rare quality, but there is not even a minor measure of consistency when health agencies reiterate that “public health is purchasable” and through all of the media of education advise preventive

services and early diagnosis and treatment and, at the same time, are inattentive to the ways and means whereby the benefits so attractively described may be realized. Not for long can public health workers continue to satisfy their appetite for real contributions and solid accomplishments with such a thin broth of activity.

The official position of public health with respect to the social movement typified by health insurance was defined by the Declaration of Principles adopted by the American Public Health Association in 1940. The Association recommended that health officers “participate with other governmental agencies and with voluntary bodies in planning for the improvement, coördination and extension of medical care.” A written principle, no matter how impressive, remains meaningless and innocuous unless and until it is transformed into action. Participation implies something positive; it implies that public health has something definite to contribute to the improvement, coördination, and extension of medical care, dental care, nursing, hospitalization, and the other health services. In short, it implies that public health and health insurance complement each other.

Among those who administer state plans of non-profit health insurance there is a growing recognition of a principle that was discovered by public health many years ago, the principle that successful administration of a state program depends upon the strength and efficiency of local organization. This recognition can lead only toward one of two decisions. The first is to strengthen the organization of health insurance by utilizing the services of an existing local agency; the alternative is to organize a new local agency. What existing local agency would be the logical choice in a coöperative arrangement? The answer seems to be clear; the health department is the only local organization pri-

marily concerned with the health services and its participation is indicated by the very nature of its own work, its own objectives, its own principles.

This is not a plea to save the existing public health organization nor a warning that hurried defensive action should be taken to forestall the development of a new administrative agency. There is a much more fundamental reason for a close working relationship between administrative public health and health insurance. That reason has nothing to do with the survival of the public health agency for the sake of survival; it has much to do with the enrichment and the conservation of human life. The primary question before public health is not what it may get through a close administrative relationship with all forms of health insurance but rather what values it has to contribute.

High on the list of values is the concept of preventive health services. An examination of the existing health insurance plans forces the conclusion that prevention is a rare element. This is not a criticism of those who conceived the plans; it only emphasizes the point that those who think in terms of prevention contributed little to the planning. Had public health workers participated, even those plans that provide limited services might have included more preventive care. As an example, the most limited medical plan includes obstetrical care but the service is sharply defined—it begins with labor and ends with delivery. Antenatal and postpartum care have been excluded from the contracts for services and those contracts cover hundreds of thousands of women that represent hundreds of thousands of missed opportunities for those who make public health their career.

The same situation obtains in the limitation upon the use of hospital facilities for diagnostic purposes. Here is missed the opportunity to further the

early diagnosis that public health advocates as the essence of case finding and of prevention. When the more comprehensive plans exclude the treatment of venereal diseases upon a basis of some hazy assumption that self-supporting people will receive service from "the state" and when other plans build a barrier between subscribers and physicians by making charges for "first calls," as a clumsy device to control the demand for services, it is obvious that the preventive concept, the importance of early treatment, and of easy rather than difficult access to the physician carried too little weight in the planning. It is not only the correction of the defects of past planning that should interest those in public health. The future plans are now being fashioned, plans that involve expansions of hospital care and medical care and plans that extend into dental services and nursing care. Think of the vistas that may present themselves to public health workers who carry to the planning conferences what they know about public needs.

Whether local health departments should or would participate in the actual administration of health insurance may be debated endlessly. But whether the qualities and the disciplines that comprise public health administration are a valuable asset to the administration of health insurance is subject to little question.

No one can minimize the importance of the training and experience in the ways and means of education, in the practical application of statistical methods and in the technics of analyzing community problems and needs. And added to these is the quality of dissatisfaction that expresses itself in administrative research, seeking new and better answers to old problems, seeking first answers to new problems as they appear. All these and more make up public health administration and all

have their places in the administration of health insurance.

There is no implication here that the health administrator by his present training and experience is fully equipped to participate in the organization and administration of health insurance. What he does have is a solid foundation to which may be added new knowledge and new skills in the same manner that they have been added before—by reading, by discussion, by observation, by postgraduate courses, and by graduate training.

In the history of public health there have been a number of periods when the question of expansion presented itself and pressed for an answer. From each of those periods public health emerged with a broadened field of activity. Another such period is here.

The initiation of health insurance and its growth to the present status place the issue and the tangible methods of participation squarely before the public health workers throughout the country.

From Social Security to Public Health in Chile*

HERNAN ROMERO, M.D., F.A.P.H.A.

Director, School of Public Health and Professor of Preventive Medicine and Hygiene, School of Medicine, University of Chile, Santiago, Chile

A FRENCHMAN once said that society creates injustice and the law tries to correct it. The wave of optimism which swept the world after the last World War and which gave birth to the League of Nations, the Hague, and other institutions was as well intentioned as it was incapable of assuring a permanent solution. That wave of optimism reached Chile, but only after a certain delay. Men who were public spirited took this initiative and tried to apply it, out of a sense of purest social justice. As a result of these movements, a series of laws of social security and protection to the weak came into being, profoundly affecting the organization of the country, the practice of medicine, and the present and future of public health. Among these laws we should mention:

1. The law of compulsory insurance against illness, disability, and old age, which takes in the wage earners in the lower brackets. This law provides benefits not only for the person insured, but for his wife during pregnancy and for his children under 2 years of age. The contributions consist, generally speaking, in percentages of the salaries amounting to 2 per cent for the worker, 4 per cent for the employer, and 1½ per cent for the Government. It includes medical, surgical, and dental at-

tention, medicines, hospitalization, and weekly cash allowances up to one year. Complete, permanent disability pensions vary between 50 per cent and 100 per cent of the last year's salary. Old age pensions, effective at 55, 60, or 65 years of age, as may be requested by the pensionee, depend on the number of contributions made. Under this law, at present, more than one-fourth of the citizens of Chile receive benefits, and if an amendment to the law now pending in Congress, is passed, it will provide for insurance to each member of the worker's family, bringing the total of persons insured under this law to around three-quarters of the population of the country. It is pertinent to observe that the farm laborer, who in our countries usually receives less consideration, has equal rights with the urban worker.

2. In contrast to the provisions of the above mentioned law, the workmen's compensation law, although it establishes the personal responsibility of the employer, allows him to meet this responsibility either personally or by insurance of his employees through a semi-governmental or commercial company. Because of this choice, only one-fifth of the eligible workers are insured. For purposes of compensation, in addition to accidents, 13 types of poisoning and 23 occupational diseases are included. The beneficiary is entitled to medical care until he is either cured or pronounced disabled, and to

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

allowances ridiculously insufficient to provide for his needs and those of his family. No systematic effort is made toward accident prevention or rehabilitation. An amendment is under consideration which will make insurance compulsory, increase the allowances, and provide for accident prevention.

3. Hospitals in Chile, established by private philanthropy, have been by tradition almost entirely devoted to the care of the indigent. In 1932, these hospitals were grouped together under the control of the State, and their income increased by appreciable governmental contributions, as well as by the fees paid for the care of the insured. In this way almost all hospital care, as well as a great part of the care in outpatient departments and sanatoria, is a monopoly of the State.

4. The so-called Preventive Medicine Law compels both workers and employees to submit to periodical health examinations for the early diagnosis of tuberculosis, syphilis, and heart disease. When one of these diseases is recognized in a curable stage, the patient is entitled to complete or partial rest, receiving, respectively, either his whole salary, or half of it. During this period and for 6 months thereafter the employee may not be discharged from his position. For the purpose of this law, $2\frac{1}{2}$ per cent of the gross income of all social security institutions is set aside, plus 1 per cent additional contribution from the employers. This 1 per cent is devoted entirely to the so-called preventive rests.

5. Finally, there are in existence social and economic insurance banks, which we call *Cajas*, for public and private employees, for members of the armed forces, etc., which total some forty. Some of them are combined in a so-called National Medical Service. Although they provide some medical and dental attention and comply with the provisions of the law of preventive

medicine, they are more nearly of an economic nature. They provide retirement pay, disability and old age pensions, unemployment allowances, and loans for the purchase of property. This has contributed in a positive manner to the subdivision of land.

All these systems are based on three contributions: that of the insured, which gives him a sense of right to these services; that of the employer, who has a very practical interest in the welfare of his workers; and that of the State, to make for a more equitable division of the country's wealth. The spread of these insurance systems throughout wide sectors of the population may have influenced greatly the *esprit de corps* among our laborers, as well as the development of labor unions and political parties, which inspire, in a great many Chileans, what might be called a healthy fear. The decisive participation of the State in these organizations and its consequent control of them is, obviously, contrary to liberal thought, but is entirely in harmony with the duty of the State to protect the health of its people, as recognized in our constitutions, and with that of the individual to maintain his health both for his own good and for the good of others.

There exists a consensus of opinion to the effect that these laws have serious defects in their financial and economic bases, that the number of their provisions render their administration unwieldy, and that they have not fulfilled their purpose. This failure is indicated by the fact that they have shown no perceptible influence on the general morbidity and mortality of the country. They have promoted the accumulation of considerable capital in a country where this is scarce, and have thus become a force to be reckoned with. They have enhanced the power of the State to a degree which may one day constitute a danger, if used un-

wisely. It may burden industry and add to the cost of production while raising the standard of living of the worker. Among the effects, both favorable and unfavorable, which this system has produced in the field of health and medicine should be mentioned the following:

1. Social medicine to a degree unequalled in any other part of the Western World. Almost all doctors in Chile receive salaries from one institution or another, and these salaries constitute, for many, the major part of their income. As a consequence, private practice is rapidly disappearing.

2. A growing preoccupation with mass medicine, so much so that even private practitioners pretend an interest in it. Perhaps as an indirect result of this, doctors are taking a more and more active part in national politics.

3. Augmented and improved medical attention which now reaches people of small means and isolated districts.

4. Consequent increase in the number of hospital and sanatorium beds, although not yet to a satisfactory degree.

5. Greater impetus to health education, which has existed for some time in the public health service and which other institutions have now undertaken in a sincere, although not always effective, form.

The social security plan was created and developed when the sanitary service, although relatively well established along European lines, still lacked a concrete structure adequate for the conditions of the country. Naturally it took second place as compared with the other forms of individual medical attention. Its income, derived entirely from the national budget, does not amount to as much as 5 per cent of the total expenditure for health and medical care.

The public health man must be realistic. He must not waste his ener-

gies in bewailing a state of affairs or in a futile attempt to stem a current stronger than he. Whether you believe in the virtues of social medicine or not, in Chile you can neither belittle nor destroy it. In consequence, we do not propose to construct an edifice of public health to oppose social security. Rather we are trying to steer a new course toward disease prevention and the defense of health. Within this concept, social security becomes the platform for public health or, better, we might say that social security is public health. Let us review, briefly, what we have accomplished and what we have yet to do.

The workmen's insurance institution now undertakes attention to the children of its insured up to 2 years of age. For this purpose it has established a chain of stations throughout the country where trained pediatricians periodically examine them and furnish cow's milk free to those who are not breast-fed. Simultaneously, obstetricians examine the mothers during pregnancy and, with the help of midwives, take care of the delivery and puerperium. Every working woman belonging to this, or any other Caja is entitled to a maximum of 6 weeks' rest with full pay both before and after delivery. As children under this care constitute a fourth of the population up to 2 years of age, this measure may have contributed decisively to an appreciable decrease in infant mortality. Figures likewise reveal a decrease in maternal and neonatal mortality, and this may be attributed in large part to the obstetricians and midwives of the insurance fund.

Some ten years ago the President of the Republic was empowered to declare obligatory the pasteurization of milk in such zones as he might indicate. This he has done in certain cities, among them Santiago, which has almost one-fifth of the population of the country.

The same workmen's insurance bank has constructed or purchased several pasteurization plants and, indeed, has virtual control of all pasteurization. At the same time, canned milk has become very popular. Both these measures have contributed to a definite improvement in the quality of milk sold, and probably to a consequent diminution in infant mortality and the incidence of enteric infections.

The preventive medicine law has already performed some 600,000 systematic health examinations through which it has been possible to institute treatment and rest for cases of tuberculosis, syphilis, and heart disease, when curable. Nevertheless, its greatest accomplishments have been the organization of medical groups, permanently located in some parts of the country and ambulatory for smaller districts, composed of doctors, dentists, nurses, special workers, and auxiliary personnel, having at their disposal x-ray, laboratory, electrocardiographic, and other equipment. Moreover, and this is of major importance, it has given us a truer picture of tuberculosis throughout Chile. Thanks to this more than to any other factor, we now realize that tuberculosis in Chile is in the epidemic stage and, consequently, we have oriented our campaign toward the suppression of the sources of infection through isolation of the infectious cases or their ambulatory treatment through pneumothorax.

The public health service, the workmen's insurance, and the social welfare offices have recently pooled their resources to undertake a national campaign against venereal disease. Clinics have been established in Sanitago, Valparaiso, and three southern provinces, where free treatment is given to the insured and destitute, where there is epidemiological investigation and better control of prostitution. Among other interesting developments are the provision of beds for the isolation of in-

fectious cases and the treatment, with very satisfactory results, of some thousand cases of syphilis through the continuous drip method or through frequent large doses of arsenicals.

Thanks to the efficacious and generous assistance of The Rockefeller Foundation, there has been established this year in Santiago the first full-time health unit, long an aspiration among us. In this unit we have tried to bring together all the resources offered by the various institutions mentioned earlier, to unite them in one integrated system of health protection. Among the achievements, special mention should be made of the fact that, for the first time, it has given to public health nurses the place they merit, and that it has undertaken a health survey which has already covered some 8,000 families. An equally modern program is under way in the city of Antofagasta, due exclusively to national initiative.

We firmly believe that these health units will be one of the forces through which we can bring together and direct the resources of social security and welfare, together with those of public health, toward a mass medicine which will be essentially preventive in character. The recently created Public Health School, which will open next April, will constitute another force. Its students will be made up of doctors recently graduated or who belong to the national Public Health Service, the insurance institutions, or other agencies of public medicine, and they will be taught the principles and practice of public health: statistics, epidemiology, health administration, sanitation, and later nutrition and industrial hygiene. We shall try to permeate and inspire medical agencies in our country with a new spirit of public health.

It should be mentioned here that this school is a result of the combined efforts of the University of Chile, the Public Health Service, the Bacterio-

logical Institute of Chile, and The Rockefeller Foundation, and that it will be provided with the most modern of laboratories and equipment by the Institute of Inter-American Affairs. Thanks to the generosity of these two American organizations, and also to the Pan American Sanitary Bureau and the Kellogg Foundation, an appreciable number of our doctors, nurses, and engineers are coming to the United States to complete their public health training. They are to hold important positions in the School of Public Health and in the various medical and public health organizations. It would be no exaggeration to say that this group of young and enthusiastic workers will constitute our first line in the advance of public health.

Throughout the world the public health service has outgrown the small, primitive agencies designed to defend the borders against the invasion of disease, or to combat endemic plagues, or to cope with national disasters or other

emergencies, or to take care of local problems, generally of a cleanup nature, which today are somewhat looked down upon. It might also be created, *ex-novo*, to control situations engendered by community life. But Chile was the first country in America to establish social security, and its experience, both favorable and unfavorable, has served as a guide for similar legislation in others of our countries. Chile has carried it forward and diversified it to a degree unknown in any other democratic nation, and in this same soil, public health will flourish. It is questionable whether our example is worthy to be followed, because the road has been a long and tortuous one, exhaustive both of money and effort. At any rate, it is evident that our case constitutes a source of observation and meditation for those interested in social security and public health and the relationship between the two. It is clear, too, that it offers us vistas both wide and incomparably intriguing.

The Proposed Canadian National Health Bill*

J. J. HEAGERTY, I.S.O., M.D., C.M., D.P.H.

Chairman, Advisory Committee on Health Insurance, Department of Pensions and National Health, Ottawa, Canada

CANADA has been careless of the health of her people. This is indicated by the high death rates which prevail. It has been thought in Canada that every person was capable of earning an income sufficient to provide his own health needs and those of his family. The depression showed we were wrong, but the depression alone was insufficient to cause legislators to take steps to provide the people with adequate housing, nutrition, and health facilities. It needed a war to do so. Indifference, neglect, and special privilege have stood in the way of improving living conditions and of reducing morbidity and mortality. Health departments have never had sufficient funds nor adequate leadership comprising personnel fully trained in various public health activities.

Not only are death rates in Canada excessive, but the percentage of physical defects is high. Forty per cent of recruits suffer from physical defects. In a study in one province of Canada it was found that 70 per cent of young people between the ages of 13 and 30 have one or more remediable defects. Some of these are serious. Maternal mortality, infant mortality, tuberculosis, venereal diseases, and mental diseases are excessive. Diseases of middle age, such as heart disease, cancer, and

diseases of the arteries and kidneys are increasing. The solution is the adoption of a modern Public Health and Health Insurance Plan which will include a comprehensive reorganization of public health departments and the provision of full and complete medical care for all of the people of Canada.

With this object in view the Honorable Ian A. Mackenzie, Minister of Pensions and National Health, in May, 1941, issued instructions to the officials of the Department of Pensions and National Health to discuss the subject of the health of the people of Canada at the next meeting of the Dominion Council of Health with the object of initiating a comprehensive study of public health and medical care leading to the adoption of a Public Health and Health Insurance Plan for the Dominion. To this meeting were invited representatives of the Canadian Medical Association, Canadian Hospital Council, the medical faculties of universities, the Royal College of Physicians and Surgeons, and voluntary health organizations, as well as representatives of interested governmental departments.

The Director of Public Health Services presented the subject of public health and medical care for discussion. Deficiencies in the field of public health were stressed and particularly those respecting tuberculosis, mental diseases, maternal mortality, infant mortality, and the diseases of middle age, all of which are controllable by known public

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

health measures. The discussion brought out the following facts:

Both incidence and mortality of tuberculosis are excessive. Moreover, the rate of reduction of mortality is much more rapid in some provinces than in others and especially in those provinces in which adequate preventive and treatment services are provided. A striking feature of tuberculosis is the high mortality rate in Quebec and the Maritimes. It is believed that the most effective factor in the reduction of tuberculosis is free treatment integrated with preventive services. Tuberculosis should not exist in any civilized community. The presence of tuberculosis in a community is an index of lack of interest in the health and welfare of the people.

In respect of mental diseases, it was made clear that the situation is grave. The number of cases is increasing. There is a shortage of 10,000 beds and there are many mentally ill persons walking the streets for whom no accommodation is available. It is the Canadian experience that more beds are utilized for the treatment of mental illness than the total number of beds required for the hospitalization of all other diseases. Apart from the question of accommodation, there is lack of professional staff—doctors, nurses, and other personnel. Many providing services for mentally ill persons are inadequately trained and facilities for occupational therapy and recreation are few. The number of psychiatric clinics is small. There is no organized system of supervising discharged patients, of finding work for them, of teaching them to care for themselves, or of teaching their families to care for them; nor is there a program of vocational guidance and training for mental defectives. Organized community care is negligible. Although it is known that we should be concerned with problems of mental health relating to earliest childhood.

school age, working life, and home life, little, if anything is done in that direction. The seriousness and scope of the mental problem in Canada is causing concern. In order to insure progressive improvement of all methods of control of mental illness, future planning should comprise ample facilities, including scientific research.

Statistics regarding the venereal diseases are incomplete, inasmuch as doctors, generally, do not report their cases. Nevertheless, statistical reports provided by venereal disease clinics indicate that the incidence of syphilis and gonorrhea is high. It is considered that venereal disease control measures are inadequate, and a new and far-reaching venereal disease program is necessary, as it has been demonstrated that in countries where adequate measures for the control of venereal diseases have been adopted a definite reduction in incidence has been obtained. There is no doubt that a complete program would effect a reduction not only in the incidence of the venereal diseases but in institutional and hospital care generally, as well as in mothers' allowances, old age pensions, and poor relief, all of which bear a relation to these diseases. In Sweden, approximately only 7 new cases of syphilis occur annually for every 100,000 of population, whereas in Canada at least 70 new such cases are reported by clinics alone. It is clear, therefore, that the problem is one that requires active consideration.

The maternal death rate in Canada is extremely high when compared with other countries with a similar standard of living—and, in fact, may be considered excessively so. Our experience in Canada indicates that, wherever special measures have been adopted to provide adequate maternal services, the death rate decreases rapidly.

Infant mortality parallels maternal mortality. Each year during the last 10 years Canada has lost on an average

15,000 children under 1 year of age. These deaths are largely due to causes which are preventable or controllable. Where active measures are adopted to reduce infant mortality, they are successful. For example, in certain cities of the United States in 1900, 1 out of every 6 children died during the first year of life; by 1920 the ratio had dropped to 1 in 12, and by 1940 to 1 in 21. Infant mortality is very definitely one instance where money can purchase life.

The rate of population growth in Canada over the past 30 years has been decreasing rapidly. From 1911 to 1921 the rate of increase was 34.17 per cent; from 1921 to 1931, it was 18.08 per cent; and from 1931 to 1941 only 10.8 per cent. Maternal and infant death rates, together with the aging of the population and the cessation of immigration, are a serious matter from the standpoint of the future of the country.

Communicable diseases take an unnecessarily large toll of life. This is due to inadequacy of health services and particularly of local health services. In fact, one of the greatest needs of the present day is the establishment, maintenance, and extension of local health services. The adoption of such services in rural areas would have the immediate effect of reducing morbidity and mortality of communicable diseases and especially of maternal and infant mortality.

Inasmuch as essential preventive services are inadequately provided throughout the country, it is clear that new measures must be formulated and adopted. In the realization that the adoption of such measures requires a broad and comprehensive plan to cover the entire country, a Public Health and Health Insurance Bill was prepared. For the purpose of formulating such a plan, it was considered essential that the views of the most representative groups in the country should be ob-

tained. For this purpose, an Advisory Committee on Health Insurance was formed. This committee, after formulating a general plan, requested representative groups throughout the country to create public health and medical care committees. The following organizations formed such committees:

The Canadian Medical Association
The Canadian Dental Association
The Canadian Pharmaceutical Association
The Canadian Nurses Association
The Canadian Hospital Council
The Catholic Hospital Council of Canada
The Canadian Public Health Association
The National Council of Women
The Catholic Women's League
The Federated Women's Institutes of Canada
La Federation des Femmes canadiennes francaises
The Canadian Welfare Council and Canadian Association of Social Workers
The Trades and Labour Congress of Canada
The Canadian Federation of Agriculture
The Canadian Manufacturers Association
The Canadian Life Insurance Officers Association.

The great majority of these organizations made direct representations and approved the general principles laid down in the draft Health Insurance Bill.

Perhaps the culminating achievement of the Advisory Committee on Health Insurance, aside from the draft proposals which constitute its report, was the unprecedented assembling between annual conventions, for the first time in 75 years, of the General Council of the Canadian Medical Association, when this great and influential body formally went on record in favor of the principle of health insurance.

The modern conception of health insurance is the reduction of morbidity and mortality by prevention and treatment, and it was with this object that the Advisory Committee on Health Insurance drafted a combined Public Health and Health Insurance Bill.

Subject to the provision of this draft Bill, the Governor in Council may make an agreement with the Lieutenant-

Governor in Council of any province to make grants for public health and medical care, provided that the province makes provision for utilizing both grants. The grants are specified in the First and Third Schedules to the Bill and the proposed statutory provisions are contained in the Second Schedule.

The draft Bill is based on compulsory and contributory insurance. It is planned to include all persons resident in Canada by agreement with the provinces. It is considered essential that everyone in Canada should be provided with health insurance; nevertheless, no compulsion is placed upon the provinces in this respect other than that all indigents must be included in the plan.

To provide health insurance, it will be necessary to create a Health Insurance Fund comprising money contributed by insured persons, employers, Provincial Governments and the Dominion Government. By so distributing the cost, the financial burden will be considerably lessened.

After careful thought and consideration, it is believed advisable from the standpoint of the collection of contributions to divide insured persons into two classes: "employed insured persons" and "assessed insured persons." The payment of contributions has been so devised that these classes will contribute in proportion to their wage or income. If an employed person is capable of paying the entire cost for himself and his dependents, he shall be obliged to do so. If unable to pay the entire cost, his employer will pay the difference for him, and the province for his adult dependents. The combined contributions of employer and employee will be supplemented by a Dominion grant. Assessed insured persons are the unemployed who have an income from a source other than wages, or who are indigent. Like the employed insured persons, the assessed insured

person, if he can do so, will pay the entire cost for himself and adult dependents; if not, the province will pay the difference. Financial assistance will be provided by the Dominion Government. There will be no charge for children up to a prescribed age—16 years.

As soon as health insurance is adopted in a province, all residents will be registered and classified and will be instructed to select a doctor from a list provided after consultation between the Provincial Health Insurance Commission and authorized medical committee appointed for the purpose. If the insured person wishes, he may select a clinic instead of a private practitioner.

The method of payment of physicians, nurses, and others will be left to the decision of the Provincial Health Insurance Commission. Also, it is considered desirable that the services of the physician should be utilized for prevention as well as treatment. Thus, the physician will have a responsibility for the health of each member of the family and be responsible for public health measures designed to reduce morbidity and mortality. He will act as counsellor and adviser in respect of the health of the family as a unit.

The benefits comprise prevention of disease and the application of all necessary diagnostic and curative procedures and treatments, including medical, surgical, obstetrical, dental, pharmaceutical, hospital, and nursing benefits and such other ancillary services as may be deemed necessary. Provision is not made for cash benefit due to unemployment caused by illness, as it is considered that such benefit should be provided by other means.

Medical benefits include the services of a general practitioner, consultant, specialist, surgeon, obstetrician, hospitalization and nurse, and ancillary services. Nursing in the home is con-

fined to the visiting nurse, except where the circumstances are such that bedside nursing is essential.

Dental benefit must of necessity be restricted, as the number of dentists in Canada is insufficient to provide full and complete dental care for all. It is proposed that a committee of the Provincial Dental Association shall make an arrangement with the Provincial Health Insurance Commission to provide every child up to 16 years of age with a semi-annual dental examination and such reparative dentistry as is needed. Dental care may be provided others to the extent that the funds and the number of available dentists will permit.

Pharmaceutical benefit shall be provided in accordance with a list of drugs to be drawn up in coöperation with the Provincial Health Insurance Commission and a committee of the Provincial Pharmaceutical Association. Special provision may be made respecting drugs and pharmaceutical preparations known as specialties.

Hospital benefit is to include general ward services unless the insured person wishes by paying the difference to obtain semi-private or private room. In special cases accommodation other than general ward may be provided. The terms of agreement for hospitalization will be arranged by the Provincial Health Insurance Commission with a committee of the Provincial Hospital Groups.

Nursing benefit, outlined above, will be provided by the Provincial Health Insurance Commission in coöperation with a committee of the Provincial Nursing Groups.

Provision is made for administration through a Health Insurance Commission in each of the provinces. In considering the question of administration, it was the opinion of the Chief Medical Officers of Health of the provinces and the Advisory Committee on Health In-

surance that administration should be by the Government for the people through Provincial Departments of Health. Nevertheless, the Canadian Medical Association and other professional and lay groups favored a commission. In view of this preponderance of opinion, provision has been made in the draft Health Insurance Bill for a commission comprising a chairman who shall be a doctor of medicine, the Deputy Minister of Health of the province (ex-officio), and such other number of persons as may be determined from time to time by the Lieutenant-Governor in Council after consultation with representatives of professional groups, labor, agriculture, industry, women's organizations, etc.

Provision has been made to provide benefits only after the Health Insurance Commission has consulted with professional groups providing benefits but, should these groups not coöperate, the Health Insurance Commission is empowered to appoint committees for the purpose. The Health Insurance Commission is obliged to study the resources of the province and facilities available for providing benefits and to divide the province into health insurance administrative and public health areas.

The supervision of the provision of benefits is to be placed under Regional Officers.

The Health Insurance Commission may be authorized by regulation to establish such committees, councils, or other bodies or instrumentalities as may be deemed advisable for consultative, advisory, and executive purposes as well as for obtaining effective coöperation in the administration of the Health Insurance Bill. The constitution, duties, and powers of such committees, councils, etc., shall be prescribed by regulation.

Inasmuch as Dominion administration is confined to the administration of Dominion grants, it is not considered

necessary to create a Dominion Health Insurance Commission, as administration may be carried out by a Health Insurance Division in the Department of Pensions and National Health under a Director of Health Insurance.

One of the chief disadvantages of administration of health insurance provincially is decentralization. To overcome this, provision is made in the Bill for the creation of a National Council on Health Insurance, comprising the Director of Health Insurance as chairman, the chief medical officer of health, as well as the chief administrative officer of health insurance of each province which has established a health insurance act, and such other persons, comprising a representative of the doctors, dentists, hospitals, pharmacists, nurses, labor, industry, agriculture, and urban and rural women, respectively, as may be determined by the Governor in Council. None of these will receive remuneration but will be paid travelling expenses and maintenance.

The various Grants contained in the draft Bill are as follows:

A Health Insurance Grant to assist the provinces in providing health insurance benefits as outlined.

A Tuberculosis Grant to help provide free treatment for all persons suffering from tuberculosis, including the provision of additional buildings and bed accommodation. The reduction of mortality in those provinces which provide free treatment indicates that the provision of free treatment is an essential to the elimination of tuberculosis.

A Mental Disease Grant to assist in the provision of free treatment for those suffering from mental illness, including the provision of additional buildings and bed accommodation. In this field, Dominion assistance is urgently needed.

A General Public Health Grant to assist the provinces in establishing and maintaining public health services commensurate with the needs of their people. The same problem has

confronted the United States and has been solved by the provision of funds to raise the per capita expenditure on public health and to meet special needs.

A Venereal Disease Grant to aid in providing preventive and free treatment for persons suffering from venereal diseases on the same basis as the original Dominion venereal disease grant of \$200,000 which was discontinued in 1932.

A Grant for Professional Training to afford financial assistance to doctors, sanitary engineers and others who wish to take university courses leading to degrees in public health.

An Investigational Grant to enable the provinces to carry out special public health studies. It has been found impossible to carry out studies in public health and to provide skilled personnel during epidemics because of lack of funds.

And a *Crippled Children Grant* to prevent and control crippling conditions in children.

It will be clear from this brief summary that, apart from the reduction of morbidity and mortality of disease, the primary object is the integration of public health and medical care for the purpose of raising and maintaining the standard of health of the people.

The draft Bill as outlined above has been presented to a Special Committee on Social Security of the House of Parliament and has been approved in principle by that committee. The plan has been discussed with the Ministers of Health of the Provinces, who are coöperative.

In addition, the Dominion Government has passed a National Physical Fitness Act creating a National Council on Physical Fitness and a Physical Fitness Fund. The object is to co-ordinate the efforts of all governmental and other agencies engaged in the field of physical development, physical culture, sport and recreation.

NOTE: A Committee on Finance is at work on the question of collection of contributions. It is probable that the method recommended in this article will be modified.

The Evolving Pattern of Tomorrow's Health*

Future of Public Health in the Western Hemisphere

FELIX HURTADO, M.D.

Undersecretary of Public Health of Cuba, Havana

THE science of public health, which has undergone an extraordinary development in recent years, during which many allied disciplines have been incorporated with it, constitutes at the present time a true specialization, indispensable for the care of health in communal life. Outstanding among these specialists we find the physician and engineer as fundamental elements of the whole public health structure. They must needs be helped by a series of experts, also important, and in which auxiliary group we must signally mention the public health nurse.

Many years have gone by since the time of that elementary public health, indeed purely a sanitary police in its methodology, which covered the first period of preventive medicine with the establishment of so-called quarantines. These were representative of the spirit of sea-going men, and of those in care of the debarkation ports of these great continents, to whose ports flocked tidal waves of immigrants from Europe in search of religious freedom. This was to be the foundation of the Thirteen Colonies—bulwark of the North American nationality, today grown into this formidable and vigorous country, principal champion and defender in the titanic struggle of the democratic

countries of the world against the enslaving onslaughts of the totalitarians.

These early concepts of health have steadily been changing to a more thorough and ample preservation of the health of the conglomerate inhabiting our countries. Such a function has grown until it has become a primary duty of the State. It is clear, of course, that in speaking of health we must fundamentally take into consideration the environmental living conditions. These include the habitation itself, the clothing and the nourishment of the individual, his habits and customs, his physical and intellectual education. In brief, the present conception of public health acquires importance whether the point of view from which we study it be properly technical in its medical aspect, or be it political, in respect to the responsibility of the State.

Public health, born in the way we have very summarily described, pursued its development—although rather unequally—in the countries of our two Continents, becoming the exponent of hygienic culture of each one, and conditioning the development to political, social and economic factors. Nevertheless, it may be set forth that in this protracted period there were marked examples of the effort and firm desire of the nations of America to rise against many obstacles and to improve their public health standards. No better proof of this assertion exists than the

* Presented at a Special Session of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

magnificent pages written in medical and public health history by the glorious research and public health accomplishments indelibly linked with the names of Finlay, Reed, Oswaldo Cruz, Liceaga, Carrion, Guiteras, Gorgas, Lebrede, and many more gallant soldiers of the common good, distinguished in the public health struggle in this hemisphere.

The circumstances of the universal conflict in which the United Nations are involved, in defense of human liberty and welfare, have thrown us more closely together and given greater cohesion to our ranks. This has powerfully contributed to a greater knowledge among ourselves, the creation of a real and solid friendship among the peoples of our Continent, and to give vital and objective expression to what was at first a philosophical enunciation: "The Good Neighbor Policy." We are living, therefore, a real and positive application of this doctrine, whose propounder, President Roosevelt, set it forth under the dictates of a sentiment of fine sincerity. The Pan American Sanitary Bureau, that wonderful organization for inter-American connection, endowed with high and extraordinary functions, has done much, under the tactful leadership of that highly respected Pan American figure, Dr. Hugh S. Cumming, its Director General, ably helped in his strenuous work by the tireless secretary, Dr. Aristides Moll.

Parallel to the development and growth of the United States Public Health Service, there was created a society to discuss and consider the scientific principles, the new discoveries, which serve as a base to public health measures; thus was born the American Public Health Association, a splendid organization, model and standard in its class, which is making a signal contribution to the war effort by holding this 72nd Annual Meeting, in which there are present as participants a large Latin delegation through the invitation of the

Association. It would be foolish to deny the extraordinary importance of the combined action of these organizations, whose activities are linked in a practical way through the corresponding public health officials, and which at the same time extend benefits to the whole hemisphere by means of the coordinating mechanism established through the Pan American Sanitary Bureau.

If in times of peace these connections represent a prime factor in the machinery of applied public health science, in times of war this importance is enormously multiplied. The sanitary factor is of paramount value in all respects, as in the mobilization, selection, and training of front-line troops, or in the hygienic and medical care of the enormous civil home-front, the civilian production and supply battle-front, which has given the present war its characteristic of active participation of all elements.

Gone are the times when communications were slow and difficult. The astonishing marvels of oceanic travel given us by those fast ships that sailed to Europe from American shores in but a few days' passage, have shrunk to invisibility before the fantastic speeds attained by aerial travel, which today consume in a world-girdling trip the time before spent in journeying between not-so-distant cities. This speed of travel, which is a wonderful exponent of the progress of mechanics, at the same time destroys and annuls the barriers heretofore erected for our protection and isolation. In spite of science's advance and conquest, there still exist, in different places of the globe, foci in which certain causes of disease have established strongholds—agents capable of causing terrible infectious diseases, of maintaining grave endemic diseases, and which from time to time break out of bounds, invade great territories in deadly epidemics, and not so rarely reach such proportions in time

and space as to constitute pandemics.

The centers of research have indeed made gigantic efforts to study and ascertain the causes of disease, contributing to the exact knowledge of the causative agents, and therefore opening the road to preventive treatments, often placing in the hands of the public health specialist the proper immunizing vaccine. In this position, happily, we find ourselves in the fight against yellow fever—that deadly and vicious tropical plague—the discovery of whose vector belongs to the genius of Carlos Finlay, its experimental proof to the American Commission, and its preventive immunization to the technicians of The Rockefeller Foundation, enabling present-day control of the disease. Cholera, bubonic plague, diphtheria, tetanus, and many more, are today diseases which can be prevented by the use of correct immunological procedures employing the corresponding vaccines.

But infection is not the only aggressor to undermine the individual's body through diverse maladies; there are other bodily ills derived from the absence or deficiency in the organism of food. It thus becomes necessary to consider the sanitary control of foodstuffs as one of the factors preserving that physiological equilibrium called health, and it is clear that in this respect sanitary controls are indispensable and encompass a very ample field. This second aspect of foodstuffs gives us a new and most extraordinarily attractive field, that of agriculture and industrial hygiene. The simple mention of this brings to mind its vast extension and all the possible divisions to which its study may be directed. We may thus consider foodstuff conservation and distribution in its social and hygienic perspective.

Thus reviewing the subjects mentioned, we realize how very ample is the matter comprised, not only in its extent, but also in its depth and implications. This places the rôle of all officials of

public health departments on a highly important and responsible plane. Be they named ministries, secretaryships or departmental agencies, all are indubitably organizations essential to the fulfillment of a basic function of the state.

All these considerations explain the existence of different sections in the American Public Health Association, and also the different divisions that function in the United States Public Health Service.

We do not wish to ignore the opportunity to underline the wonderful contribution to the progress in hygienic attention of the habitation and habitat represented among the specialized services by the public health engineer. He is the physician of the habitat, and on his shoulders weigh at present great and important responsibilities. Public health engineering must be well respected wherever it is desired to reach the minimum standard of the life of human beings.

War requires special controls to assure the vigor of the soldier and his physical integrity. Health agencies, both military and civilian, are therefore elements on which the greatest efforts are concentrated in order to win the war. It is essential that we develop for these needs a new kind of public health expert, specializing in a complex science, integrating many fractions of allied sciences and characterized in all things by an essentially preventive way of thinking. If we are to do our duty to these ideals we require a coördinated collaboration among all responsible elements of the Continent. There is no better instrument, in my opinion, to bring this about than the combined action of two organizations of great prestige, standing and consideration in the Continent: these are the Pan American Sanitary Bureau and the American Public Health Association.

In view of the foregoing considera-

tions, we arrive at the following conclusions:

1. It is recommended that a joint Committee be organized between the American Public Health Association and the Pan American Sanitary Bureau with the aim of revising current legislation relating to epidemiology and anticipating prompt adoption by all nations of the continent.

2. It is recommended that the American Public Health Association offer its coöperation for the call of what we may designate an Inter-American Convention of Sanitary Coördination for the purpose of considering all points brought out in this agenda and the means for implementing an efficient public health policy throughout the hemisphere.

3. It is recommended that the Association undertake an extension of its charter in the form of a branch inclusive of those regions or states in this hemisphere not already comprised within the area of the A.P.H.A.

4. It is recommended that steps be taken in order to secure the organization of all health departments in such a way that they shall be

technically staffed in the various public health specialties and in order that they may be able to intervene in the protection of water supplies, both in cities and rural work centers, and in the promotion of immunization.

Finally, for me to draw in panoramic scope the future of public health in the American continents is an enterprise beyond my strength. Nevertheless, I have endeavored to develop the theme, moved by enthusiasm and faith in our common comprehension and our common need and with a belief in the real fraternity of the people of our hemisphere. Those of us who, in one way or another, participate in public health work in our respective countries are bound to offer our full coöperation in this work of collaboration in order that we may firmly establish those ideals so well set forth in the Atlantic Charter.

Nation-wide Victory Corps— Physical Fitness Dental Program*

J. A. SALZMANN, D.D.S., F.A.P.H.A., AND
LEON R. KRAMER, D.D.S., M.P.H., F.A.P.H.A.

Head of Dental Service, New York City Vocational Schools, Central Commercial High School; and Director, Division Dental Hygiene State Board of Health, Topeka, Kans.

WORKERS in the school health specialties have been efficiently performing an important job in dental health for many years. Since the early 1900's, school health personnel has taken the initiative in stimulating dental care among children. While the foregoing is a matter of record, the important fact has been generally overlooked that the interest in the dental health of school children on the part of school health workers, both in the public health and education departments, actually antedates present-day activities in this field of the dental profession itself.

A classic example of the initiative taken by educators in inaugurating dental care among school children is that of Willis A. Sutton, who as a public school principal of Atlanta, Ga., in 1909, interested himself in dental care for school children and succeeded in obtaining the aid of dentists in Atlanta in this work. Later, when Sutton became Superintendent of Schools of Atlanta, he instituted regularly conducted mouth hygiene periods for the children of that city. Such interest in dental health is quite common today,

but was an unheard of innovation in this country thirty-five years ago.

It has been aptly pointed out that the dentist is just as much afraid of the child as the child is of the dentist. Time was when many dentists were reluctant to treat child patients and some even boasted that they "have nothing to do with children." Those days, fortunately, are now a thing of the past. It is the exceptional child whose fear of the dentist is such as actually to keep him from receiving dental treatment. Whatever reasons exist for the lack of dental care among some of our school population, fear of the dentist is certainly not one of primarily consideration. It is the school health worker, who largely deserves the credit for this change of attitude in the child with relation to the dentist.

However, despite the progress made, the disturbing fact remains that dental defects as a cause for rejection from military service were all but abolished by Selective Service authorities in order to prevent the wholesale disqualification of selectees. This is a clear indication that the amount of dental care received by children of a few years ago was woefully inadequate.

With the virtual removal of dental standards as a cause of rejection from military service and the acceptance of hundreds of thousands of dental cripples

* Presented at a Joint Session of the American School Health Association, and the School Health Section and Oral Health Group of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

by the armed forces, dentists serving with the Army and Navy and other branches of our military and naval units are now faced with the Herculean task of treating dental disease, filling teeth, and constructing artificial dentures for the young men whose dental defects Selective Service has been forced to ignore and who have been accepted for military service. This work, it should be remembered, is in addition to the routine service needed to care for the usual dental ills that arise among the uniformed forces and the treatment of dental and oral conditions in those wounded in actual combat.

A large number of dentists have been inducted into the military services to perform this job. At the same time, the demands on the services of the civilian dentists have increased with the rise in general and war industrial employment which has made it possible for more people to afford dental treatment.

The boys and girls of our country who are too young for military service are now in danger of experiencing even greater dental neglect than heretofore for a number of reasons, foremost of which is the depletion of dental personnel in civilian practice by the induction of almost 30 per cent of the practising dentists into the armed forces.

With dentists in civilian practice largely occupied in treating adults, there is again the danger that dental treatment of child patients may be deferred or entirely ignored, repeating the vicious circle of dental neglect as it was revealed in the physical examinations of draftees.

In order to prevent the repetition of dental neglect of school children, the U. S. Office of Education, the U. S. Public Health Service, and the American Dental Association, have united their efforts in sponsoring a nation-wide dental program designed to reduce this health hazard among high school

boys and girls, especially those in the upper grades, most of whom are shortly to enter the armed forces or war industries. It is hoped that these boys and girls will be made dentally fit before they actually leave school. This program which has already been launched is correlated with the correction of physical defects phases of the Victory Corps and Physical Fitness programs operating in high schools throughout the nation. It is planned to continue the program for the duration.

Through official channels, Dr. J. Ben Robinson, President, American Dental Association; Commissioner John W. Studebaker, U. S. Office of Education, and Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, have requested dental, educational, and health officials throughout the nation to carry out their specific activities in the execution of this nation-wide dental program.

The coördination, implementation, and execution of the program on the national level has been delegated to the Victory Corps-Physical Fitness Dental Program Committee of the American Dental Association, which is composed of representatives of national dental, educational, and health groups. This committee of which Dr. Leon R. Kramer of Topeka, Kansas, is chairman, is supported and assisted by the Council on Dental Health of the American Dental Association, headed by Dr. Emory Morris of Battle Creek, Mich.

As pointed out by Dr. Morris, "The Victory Corps proposal contains no provision for assuring dental care for all population groups. However, this program should and will reach a large majority of high school students. There exist today at the state and local levels many facilities and considerable means that can be drawn upon and utilized to assist those who are unable to work out their own economic problem."

Defense, welfare, patriotic and other groups interested in the health of the youth have been invited to assist in the promotion of the program.

As a special contribution to the war effort, the American Dental Association has requested dentists in every locality to give "priority rating" and special consideration to the dental needs of high school students. This consideration is especially recommended to be given students who will soon be absorbed into the armed forces or war industry.

Letters explaining the program have been mailed from the U. S. Office of Education, in September of this year, to all state superintendents of public instruction, who are requested in turn to inform all high school principals in the nation.

Reports from dental officials indicate that approximately 40 states and the District of Columbia are now participating in the Victory Corps-Physical Fitness Dental Program which is designed to function under either the Victory Corps or other types of physical fitness programs operating in high schools in this country.

The Council on Dental Health has urged dental and school officials in every state to make some provision to carry out the intent of the program along the following lines:

1. On the state level enlist the coördinated efforts of the state department of public instruction, the state dental organization, and the state department of health. In most instances, the director of the dental division in the state board of health will be the administrator of the program.

2. State superintendents of public instruction are informed concerning the state dental society's willingness to aid school officials to carry out the dental corrective phases of their physical fitness programs.

3. The state superintendent of public instruction notifies through his bulletin or a circular letter, school officials in the state in regard to the dental society's willingness to cooperate.

On the local level the program can be carried out through the joint efforts of local high school officials, local dentists, and public health personnel.

Physical education teachers, science teachers, home room teachers, school nurses, and other qualified health personnel may participate as follows:

1. Distribute dental health forms and other material.
2. Keep records of dental health forms distributed to and returned by students.
3. Keep a record of the progress and results of the program.

It is important that *some one person* in the high school be made responsible for this program.

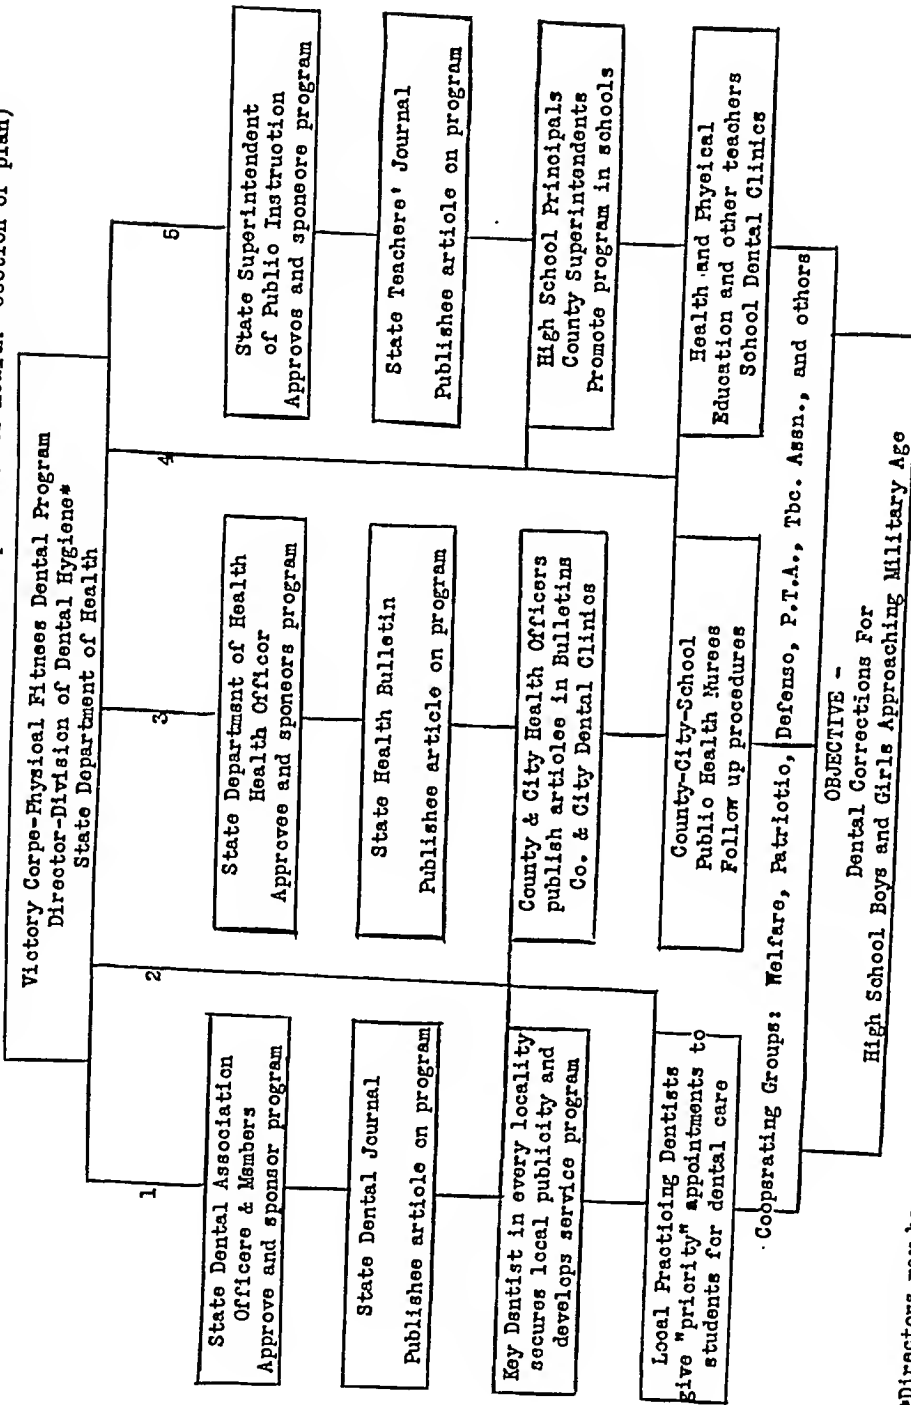

Dental posters, dental education folders, and dental report cards for students, classroom record blanks for teachers, and other materials needed for conducting the local program, in many states, may be obtained from the dental health division of the state department of public health. Educational material in the form of posters, leaflets, and dental health forms, films and other materials are also available at small cost from the Bureau of Public Relations of the American Dental Association, 222 East Superior Street, Chicago, Ill. It is suggested that local school officials and dentists develop the program to suit local conditions.

Possible sources of financial assistance include, the state or city boards of health, state or city departments of education, and state or city dental societies.

To start the program it is suggested that an announcement be made to the pupils describing the objective of the program as for example, in the form of "A Challenge to High School Students."* On the same day dental posters may be placed on bulletin boards and the distribution of dental

* See appendix.

FLOW DIAGRAM OF ORGANIZATION AND PROCEDURES FOR VICTORY CORPS AND PHYSICAL FITNESS DENTAL PROGRAMS
(States that have no dental health director may omit the "Department of Health" section of plan)

*Directors may be:

State Dental Director

Chm. State Dental Committee

H.S. Supervisor-Office of State Supt. organizations.

Council on Dental Health

2-4-Director sends instructions, local publicity, posters, dental forms, etc., through official channels to groups indicated on local levels.

American Dental Association

folders and dental health forms to the pupils is begun.

It is suggested also that, in coöperation with the local dentists, school officials develop a plan whereby pupils can receive dental examination and treatment. If dental health forms are used, they should not be given to all the pupils at one time as this would congest dental offices. The Health Committee of the Parent-Teacher Association, the School Health Council, and other organizations interested in school and community health should be invited to coöperate in the program.

The official class teacher should record the names of the pupils to whom dental health forms are given, the date they are distributed, and the date they are returned with the dentist's signature, indicating that dental corrections have been completed.

Dental inspections may be made in the offices of private dentists or in the schools in accordance with a plan mutually agreed upon by the school authorities and the local dentists.

Dental appointments: With proper safeguards, pupils should be permitted to fill dental appointments during school hours if required by the dentist.

The teacher and school nurse should frequently emphasize the importance of obtaining needed dental service and urge each student to have corrections made. Students in low income groups should be urged to pay for their own dental services by doing odd jobs outside of school hours.

At regular intervals after dental health forms have been distributed to the pupils, persons in charge of the local school program should check the results to ascertain the number of students who have obtained needed dental service.

School officials may wish to set up the objectives of this program as an achievement device in physical fitness.

Dentists engaged in administering

dental health programs realize fully that school health workers constitute the backbone of the dental program for school children. Without the educational and follow-up aid of school and other public health workers, the result obtained in the way of corrections would be extremely low. This was demonstrated in a survey conducted some few years ago by the American Child Health Association which found that in the absence of a sustained educational and follow-up service children with dental defects showed the low average of only 2 per cent corrections. These findings are a far cry from the many 100 per cent corrections so frequently reported today. Perfect scores in dental care are not possible without the active support of the school health workers. The dental profession knows fully the importance of the school health worker in dental health.

APPENDIX

A Challenge to High School Pupils

Will you be able to fulfil your duties as a citizen when you become of military age? Will you want to join the Air-Corps, the Navy, the Marines, the Coast Guard, the Army, the Nurses' Corps, the Nurse-Aids, the WAC or WAVES? Will you eventually want a job in an industry that demands good physical condition and appearance of its employees?

If you do, you boys and girls in high school should start right now to have correctable physical defects corrected.

Dental disease and sight defects accounted for about 35 per cent of all rejections for service in the Army. Virtually all rejections charged to dental defects can be avoided if corrections are made in pupils of high school age. Many of the eye defects can be minimized by treatment, or by the proper fitting of glasses. If there is any doubt in your minds relative to your physical status, consult your dentist and physician at the earliest possible time.

Remember, you have but one set of permanent teeth, one pair of eyes, one pair of ears, feet, and hands. You have but one body, to serve a lifetime. If you abuse, neglect, or

wreck a car, it can be replaced. If you neglect to make early repairs of defects in your body when they become evident, if you abuse or wreck this body of yours, you may not only have cause for regret the rest of your life, but also you may be unable to procure a job in the field of your choice.

Are you going to be one of the thousands

of young persons who, in the prime of life, cannot fulfil all the duties of citizenship because they neglected to make timely correction of physical defects?

What you do about correcting dental, eye, and other defects now, is your answer to this challenge: your answer to yourself, to your government and to your future dependents.

War Manpower Commission Extends Coverage To Include Health Workers

Physicians, dentists, veterinarians, sanitary engineers, and nurses who are salaried employees in essential or locally needed activities are hereafter subject to the same provisions of any employment stabilization program which applies to other workers in such activities, the War Manpower Commission announced. Such professional employees may not change their jobs without getting statements of availability from the United States Employment Service, or being referred to new jobs by the USES. The USES,

however, it was emphasized, will make referrals of such employees only after consulting the state chairman of the Procurement and Assignment Service. This procedure, it was explained, will insure referral of these professional workers to jobs where they can make their most effective contributions to the war effort. Upon approval of the Regional War Manpower Director, any state director may delegate the duty of referring such employees to new jobs to the state and local offices of the Procurement and Assignment Service.

Post-War Implications of Fluorine and Dental Health*

Epidemiological Aspects

H. TRENDLEY DEAN, D.D.S., F.A.P.H.A.

Senior Dental Surgeon, Division of Infectious Diseases, National Institute of Health, U. S. Public Health Service; Bethesda, Md.

THE prime problem of modern dentistry is the control of dental caries. Among civilized people few escape its attack, generally not one tooth but many being affected. As dental enamel once injured is incapable of self repair, carious defects and their sequelae accumulate at a rapid rate. If the next generation is to avoid a dental condition similar to that revealed by Selective Service figures¹ effective means of mass control, markedly inhibiting the high attack rate now characteristic of this condition, are essential.

For the treatment of the teeth and their surrounding structures there is in this country an autonomous profession of about 70,000 dental practitioners. During 1941 about \$500,000,000 was spent for dental services in the United States.² As the major portion of a dentist's time is devoted to repairing either the ravages of dental caries or its numerous sequelae, the expanding economic, social and hygienic aspects of this problem are apparent. And, despite this large expenditure of time and money, the needs of only a portion of the population were met, the majority of the people receiving either no dental

service or merely extractions. In so far as the general population is concerned there has seemed no practical means of handling this load with existing professional facilities and knowledge.

The first step in meeting this vast problem of dental needs lies in drastically reducing the incidence of dental caries in the population of the future. The recent epidemiological studies of dental caries experience associated with the use of fluoride domestic waters whose concentration is between 0.0 and 1.0 p.p.m. have opened up a hopeful potentiality undreamed of a few years ago. Concurrent studies in bacteriology, biochemistry, and animal experimentation lend further support to this hypothesis. Today much accumulated evidence indicates that small amounts of fluoride may be essential for optimal dental health. This paper will very briefly † present some of the epidemiological evidence pointing to the possibility of partially controlling dental caries attack by means of low fluorination of the common water supply.

1937-1939 PERIOD

In any history of the fluorine-dental caries relationship, the 1937-1939 period will be conspicuous. During this period a number of studies in epi-

* Presented before the Oral Health Group of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

† For a more complete review of this subject, see reference 3.

demology, bacteriology, biochemistry, and animal experimentation were reported. Noteworthy was the fact that the findings of these studies from independent investigators working in different institutions were each in general harmony with the findings of others. Briefly these studies were:

Epidemiology—In 1938 Dean reported⁴ that among school children residing in areas of endemic dental fluorosis there was a very noticeably increased freedom from dental caries when the group was compared with a similar group living in a nearby non-endemic area. This increased freedom from dental caries was *operative whether or not the teeth were affected by mottled enamel*.

A short time later a study specifically designed to test this hypothesis was made by Dean, Jay, Arnold, McClure, and Elvove,⁵ the groups studied consisting of 885 12–14 year old white children of four Illinois cities. Observations were limited to those children with continuity of risk of exposure to the variable being studied, the water supply. Attempts were made to equalize variables such as age, sex, color, and diet by sampling methodology; sunlight intensity by location of the cities studied. Two Illinois cities (Galesburg and Monmouth) using domestic water supplies containing 1.8 and 1.7 p.p.m. of fluoride (F) showed similarly low dental caries experience, 201 and 205 per 100 children examined, respectively. Two nearby cities (Macomb and Quincy) using water supplies containing 0.2 and 0.1 p.p.m. of fluoride (F), respectively, showed dental caries experience rates double and triple those observed at Galesburg and Monmouth. Epidemiological aspects of oral *Lactobacillus acidophilus* in the saliva closely reflected the observed differences in the dental caries rates between Galesburg and Quincy. The quantity of amylase secreted in

the saliva and the amount of fluorine in pooled samples of saliva⁶ disclosed no group population differences between Galesburg and Quincy. From an epidemiological standpoint it was difficult to ascribe these marked group differences to any cause other than the common water supply.

Biochemistry—Until results were presented by Armstrong,⁷ and Armstrong and Brekhus,⁸ in 1937 and 1938, with respect to the fluorine content of human enamel and dentine, there was no certain evidence of any relationship between the chemical composition of enamel and dentine and the tooth's liability to dental caries. These workers found that between sound and carious teeth there was no compositional difference in the major components, calcium, phosphorus, magnesium, and carbonate. A significant difference, however, was noted in the fluoride content. According to these workers the enamel of sound teeth has a mean fluoride content of 0.0111 ± 0.00203 per cent fluorine, while enamel of carious teeth contained 0.0069 ± 0.00111 per cent fluorine. Dentin showed less striking difference; dentin of sound teeth equaled 0.0169 per cent fluorine as compared with carious teeth dentin which contained 0.0158 per cent fluorine.

Animal experiments—In 1938 Miller⁹ showed rather strikingly that induced rat caries may be largely prevented by additions of sodium fluoride, or calcium fluoride, or iodoacetic acid to the rat's food and water. Thus it was demonstrated for the first time that it is possible to inhibit induced caries in rats by means of two substances noted for their antienzymatic properties. Miller's results with respect to fluorides were confirmed by Finn and Hodge¹⁰ and by numerous workers since. In connection with this experiment of Miller's, Harrison¹¹ reported certain bacteriological studies concerning the oral flora of the rats. He found a

temporary reduction of lactobacilli from 18 per cent to 3 per cent and 1 per cent in terms of the total acidogenic organisms associated with the iodoacetic acid and fluoride feeding, respectively. Another pertinent study at this time was that of Hodge, Luce-Clausen, and Brown¹² indicating that the interpretation of Lilly's results¹³ marked reduction in rat caries on a casein diet, might be explained on the basis of possible contamination of the commercial casein with fluoride.

Late in 1939 Cox and his associates¹⁴ reported an interesting experiment which suggested that caries resistance could be "built into the enamel." The offspring of rats fed sodium fluoride, sub-mottling dosage, during gestation and lactation showed significantly less caries than the offspring of animals not fed sodium fluoride. In this experiment, these workers point out, the fluorides apparently reached the young animals through physiological routes, placental and mammary transmission. No fluorine was given to the rats after their teeth erupted.

General—Much work on various phases of this problem have been reported since 1939, the interested reader being especially referred to the monograph, *Fluorine and Dental Health*.¹⁵ The mechanism by which fluoride inhibits dental caries still provides a fruitful field for discussion and investigation, recent studies by Armstrong¹⁶ and McClure¹⁷ indicating that the mode of action may follow one of several paths.

A STUDY OF 21 CITIES IN 4 STATES

The marked variation in dental caries prevalence between the white urban school populations of Galesburg and Quincy (Ill.) furnished a thorough example of a naturally occurring phenomenon. The evidence in this and other studies pointed presumptively to fluoride as the inhibitory agent. The next step, then, was intentionally to

expose this natural phenomenon to various kinds of verification; the soundness of this hypothesis would be in direct proportion to the degree of variation found in selected epidemiological and planned experimental studies. For the purpose of experimentally verifying this hypothesis a relatively extensive epidemiological study was planned:

1. To check this phenomenon in respect to other relations and in a large number of cases over a wide and varied range of circumstances.

2. To determine whether or not there were domestic waters low enough in fluorides to eliminate the problem of mottled enamel but still sufficiently high in fluorides to reduce markedly the incidence of dental caries.

The study^{18, 19} as finally constituted comprised 21 cities: 8 in the suburban Chicago area (Elmhurst, Maywood, Aurora, Joliet, Elgin, Evanston, Oak Park, and Waukegan, (Ill.); Kewanee, (Ill.); Zanesville, Portsmouth, Middletown, Marion, and Lima, (Ohio); Elkhart and Michigan City, (Ind.); Colorado Springs and Pueblo, (Colo.); and Quincy, Galesburg, and East Moline, (Ill.).

Some of the more important technical methods utilized in the measurement and observation of this phenomenon were:

Age, sex, and color—All examinations were limited to 12–14 year old white school children with relatively equitable sex distribution in the groups. The reason for selecting this age group is set forth in the original articles.^{5, 18}

Selection of study groups—Essentially all 12, 13, and 14 year old white public school children continuously exposed throughout life to the variable under investigation (the public water supply) were examined. To study effectively differences in dental caries experience in relationship to the mineral composition of the public water supply,

* For method of computing community index of dental fluorosis, see reference 15. Indexes of 0.0-0.4 (negative) and 0.4-0.6 (border line) are of little or no public health significance with respect to the development of endemic dental fluorosis (mottled enamel); in communities showing indexes of 0.6 or more removal of excessive fluorides from the water supply is recommended.

† A few years prior to survey, Maywood water probably contained 1.4-1.6 p.p.m. of fluoride (F). (Data compiled from: *Pub. Health Rep.*, 56:761 (Apr. 11), 1941 and 57:1155 (Aug. 7), 1942.)

it is necessary to eliminate the influence of population movements. Dental caries being a non-healing lesion, a single clinical examination of 12-14 year old children can merely record the amount of dental caries experienced during the post-eruptive life of the tooth examined. At what particular time during post-eruptive tooth life the observed lesion developed cannot be determined on the basis of a single examination in this age group. In order, therefore, that the observed carious conditions might be properly classified according to one or another particular water supply, only children continuously using the water under investigation were studied. Otherwise, dental caries developed several years previously in a high rate area might be erroneously charged to a low rate area, or vice versa. Needless to say, there should be no relevant changes in the physical set-up, source, or composition of the water supply during the period concomitant with the life of the group examined.

Clinical examinations—All examinations were made with the aid of a mouth mirror and explorers by one or the other of two commissioned dental officers of the Service. The examination schedules were numbered serially and in each city all odd numbered cases were examined by one examiner, all even numbered by the other.

Dental caries experience (or prevalence) rate—A rate reasonably defined as a measure of the caries experience of a population in these age ranges may be calculated by summing the mutually exclusive numbers of permanent teeth * in each mouth associated with past or present dental caries: (past dental caries) *a.* filled teeth, *b.* missing teeth, and (present dental caries), *c.* teeth with untreated dental caries, *d.* teeth indicated for extraction.

FINDINGS

The basic findings from the study of these 21 cities are summarized in Table 1 and Figure 1. The striking variation in the intensity of dental caries attack as evidenced by the marked differences in the amount of dental caries experience among these white urban school populations is probably the outstanding epidemiological characteristic of these data. Considering the homogeneity of these populations, the method of selecting the groups studied, and the comparability of the clinical measurement standards used, it is difficult from an epidemiological standpoint to ascribe these differences to other than the mineral composition of the public water supply.

On the basis of the order of epidemiological events and knowledge from laboratory studies one seems justified in inferring that the inhibitory agent is the fluoride present in the water supply. An inspection of the range of different fluoride concentration discloses an inverse relation in general between the amount of dental caries and the fluoride concentration of the com-

mon water supply. Relatively low dental caries experience rates are found associated with the use of domestic waters whose fluoride (F) concentrations have a range of 1 or more p.p.m. Intermediately, e.g., at concentrations 0.9 to 0.5 p.p.m., the influence is less marked than at the higher concentrations; nevertheless, the dental caries experience rates are distinctly lower than those associated with the use of the relatively fluoride-free waters.

Differences in dental caries experience rates of as much as 2 and 3 times the observed minimal were not unusual; the highest rate, 1,037, at Michigan City (Ind.) was 4.4 times that observed in the city with the lowest rate, 236, at Galesburg (Ill.). Strikingly low dental caries prevalence was found associated with the continuous use of domestic waters whose fluoride (F) content was as low as about 1 p.p.m., a concentration which under the conditions prevailing in the localities studied produced only sporadic instances of the mildest form of dental fluorosis of no esthetic or known public health significance.¹⁸

In interpreting broad epidemiological studies of this nature it is essential that the single association (in this case, fluorine and dental caries) be checked with respect to its relation to other associations, both by detailed local studies and by experimental investigations. Many chemical, bacteriological, experimental studies reviewed in the monograph *Fluorine and Dental Health* together with subsequent reports in the literature in these and other coördinative fields established the relationship of fluorine to dental caries.

Analysis of detailed local studies in this series indicate that the marked differences in dental caries experience observed in the 21 cities studied are not explainable on the basis of hours of sunshine, gross dissimilarities in the diet (water excluded), or hardness of the

water supply. A brief discussion of these three variables follows:

Amount of sunshine—Certain broad studies^{20, 21} have suggested an inverse relationship between the amount of sunshine and the dental caries prevalence; neither of these studies takes into account the influence of the fluoride intake variable. In this study of 21 cities there are two instances that warrant comment. First, in the Chicago suburban area, Maywood and Oak Park are within a one mile radius with sunshine apparently comparable. Yet, Oak Park using the fluoride-free Lake Michigan water shows a dental caries rate nearly 3 times as high as Maywood using a water slightly in excess of 1 p.p.m. Again, Portsmouth and Middletown (Ohio), cities characterized by high dental caries experience, show percentages of "clear days" as high or higher than that of Galesburg where a very low dental caries prevalence was observed. Parenthetically it might also be noted that some communities having an abundant amount of sunshine are also characterized by high dental caries prevalence, e.g., Key West (Fla.)²² where the inhabitants obtain their domestic water from cisterns, Haiti,²³ Jamaica,²⁴ and Panama Canal Zone.²⁵

Diet—With respect to diet it seems reasonable to assume, especially in the Chicago suburban area, that the food habitually consumed by the populations follows a general likeness. Hence considering the selection method used (all children of continuous residence in each community), it would seem unlikely that the marked differences in dental caries experience were due to differences in the food used in the communities. It would not seem reasonable to assume that the dietary regime (water excluded) of the 633 Aurora children was sufficiently different from that of the 423 Waukegan children to account for a difference in dental caries experience

FIGURE 2—Variation in Dental Caries Experience Rates Observed in 7,257 Selected White School Children, Aged 12–14 Years in 21 Cities of 4 States with Fluoride Concentration of the Public Water Supply according to High and Low Values of Total Hardness

rates of nearly 3 times (281 in Aurora and 810 in Waukegan).

Hardness of water—From time to time ^{20, 26–29} there has been reported in the literature an inverse relation between hardness of the drinking water and dental caries prevalence. These studies, in general, indicated that, when relatively large numbers of cities were studied, users of “hard” water had less dental decay than those using “soft” waters. Most of these studies were reported before the influence of fluoride was known. In the light of these new findings it is necessary to reexamine the old “hard” water-dental caries studies because of the likelihood that the differences in the reported amount of dental caries were due to differences in the amount of fluorides and not to differences in hardness of water. Small amounts of fluorides are most frequently found in ground waters, surface supplies being as a rule relatively free. Thus, if we compare the waters of a relatively large number of cities selected at random we are very

apt to have most of the higher fluoride waters in the “hard” water group and most of the lower fluoride or “fluoride-free” waters in the soft water group.

Analysis of the data from the 21 cities studied, particularly with reference to specific communities, indicates that the observed differences in dental caries experience is not explainable on the basis of water hardness. For example, in this study, Middletown and Zanesville (Ohio) having relatively high hard water supplies (329 and 291 p.p.m., respectively) but practically free of fluorides show high dental caries prevalence rates of 703 and 733, respectively. On the other hand, the unusually “soft” water supply of Colorado Springs (Colo.) (hardness, 27 p.p.m.) contains 2.6 p.p.m. of fluoride (F). Examination of 404 children in this city showed a very low dental caries experience, 246 per 100 children examined.

Certain data reported in Table 1 for the 21 cities studied are shown in Figure 2, dental caries prevalence being

FIGURE 3—Variation in Dental Caries Experience Rates Observed in 7,257 Selected White School Children Aged 12–14 Years, in 21 Cities of 4 States with the Total Hardness of Public Water Supply

plotted against the fluoride concentration of the public water supply with the cities divided on the basis of water supplies under and over 150 p.p.m. of hardness. No tendency of these points to distribute themselves on the basis of hardness is discernible. To analyze

these data another way the dental caries experience was plotted against the total hardness of the water supply. As may be seen in Figure 3, the plotted points are scattered at random suggestive of a very poor or nonexistent relationship. When, however, these same

FIGURE 4—Variation in Dental Caries Experience Rates Observed in 7,257 Selected White School Children, Aged 12–14 Years in 21 Cities of 4 States with the Total Hardness of the Public Water Supply according to the High and Low Fluoride Values

discrete points are connected with contour lines on the basis of whether the water contains more or less than 0.5 p.p.m. of the fluoride (F) (Figure 4) the separation and parallelism is unmistakable.

In short, these data when subjected to quantitative inductive inspection show that the fluoride factor cannot be changed in quantity without affecting the phenomenon (dental caries prevalence); fluoride seemingly constitutes an indispensable condition of this particular phenomenon. On the other hand, wide quantitative variations in another factor (hardness) may occur without noticeably influencing the phenomenon, suggestive of an association without causal connection.

DISCUSSION

From the standpoint of control measures the basic finding of this study is the relationship between fluoride domestic waters in the 0.0–1.0 p.p.m. concentration range and the prevalence of dental caries. There seemingly is little if any advantage to be gained in further caries reduction by using a water higher than about 1 p.p.m. And, as this concentration is sufficiently low to eliminate the complicating problem of dental fluorosis the question of markedly reducing the dental caries incidence through low fluorination of the domestic water supply warrants thoughtful consideration.

Theoretically the question of low fluorination of the domestic water supply for the control of dental caries would appear sound.* Because of its unusually high prevalence, dental caries seems particularly suited for control measures through a communal medium

such as the water supply. The per capita cost would be low and the concentration necessary apparently harmless. In fact, there is the added security that a recommendation to bring the fluoride (F) content of a domestic water up to 1 p.p.m. would not involve adding anything new to waters not already present in water supplies now used by probably well over a million people in this country. Furthermore, the amount suggested is considerably lower than many hundreds of thousands of these people are now using daily.

Using the observations made on the 633 Aurora (Ill.) children as a basis of comparison with the 1,008 children examined at Evanston, Oak Park, and Waukegan, Arnold³⁰ has recently estimated the magnitude of the beneficial changes that might be expected to follow after the requisite lapse of time were the fluoride-free Lake Michigan water supplies used at Evanston, Oak Park, and Waukegan raised to about 1 p.p.m. of fluoride (F):

1. About six times as many children showing no dental caries experience (caries free)
2. About a 60 per cent lower dental caries experience rate
3. About a 75 per cent decrease in the first permanent molar loss
4. Approximately 95 per cent less caries on the proximal surfaces of the four superior permanent incisors

Much investigation work, however, is necessary before a recommendation can be given for its general application. *Before attempting to convert this observed natural phenomenon into one of general usefulness specifically planned epidemiological studies must clearly demonstrate the safety of low fluorination as it might relate to other aspects of the community's general health.*

Assuming that properly planned and sufficiently complete studies demonstrate the harmlessness of long continued use of waters of considerably higher fluoride concentration than 1

* For a discussion of certain philosophical considerations inherent in this suggestion, see: Wolman, A. What Are the Responsibilities of Public Water Supply Officials in the Correction of Dental Deficiencies. *J. Am. Water Works A.*, 35:1198–1200 (Sept.), 1943.

p.p.m. for effects other than teeth, it would seem that the next step would be a practical test of this hypothesis utilizing human populations. Two cities in the 40,000-50,000 population range obtaining fluoride-free water from the same source would be most desirable. A rigidly controlled study, in which the fluoride concentration of one city's water was brought up to 1 p.p.m. and the population of both cities born subsequent to the change kept under observation for a sufficient number of years would be necessary to demonstrate that the addition of that amount of fluoride to a fluoride-free water will actually reduce the amount of dental caries in the community.

Should this crucial experiment prove successful—a large amount of presumptive evidence is encouraging—domestic waters from the standpoint of the relation of fluoride to dental health might hereafter be classified into three groups:

1. Those carrying naturally the optimal concentration of fluoride (F) i.e., about 1 p.p.m., and would therefore require no treatment;

2. Those carrying an excessive concentration of fluoride requiring the removal of the excess in order to protect the community against endemic dental fluorosis (mottled enamel), or,

3. Those deficient in fluoride to which fluoride might be added to bring its concentration up to the optimal in order to inhibit dental caries attack.

Caution Urged in Use of New Mold Called Patulin, for Common Cold

Caution in considering the efficacy of a new preparation for the common cold, called "patulin," is advised by the *Journal of the American Medical Association* for December 25. The *Journal* says in part:

"Recent reports from London describe work with a preparation called 'patulin' for the common cold. This substance is a metabolic product of penicillium patulum and has now been identified. . . ." Nearly 100 patients were treated and 85 untreated were observed as controls. "One of the patients showing dramatic improvement was Gye [one of the investigators] himself. A high proportion of the persons treated seemed to show recovery in a much more rapid and complete fashion than would have been expected without treatment. From this small sample the

statistician Major Greenwood deduced that the results in the treated group would have been most unlikely to occur from pure chance alone. In the *Lancet* a week after publication of these reports appeared a communication from three investigators, headed by Stuart-Harris, which briefly records the results of giving patulin to 100 patients with the common cold and of not treating 100 alternate persons. The proportion of cases which showed clinical improvement was substantially the same in the two groups; the writers conclude that patulin had no demonstrable effect on the course of this series of colds as compared with the natural evolution of the disease. Pending the outcome of further studies, it would be unwise to view this new form of treatment of colds with too much optimism."

Post-War Implications of Fluorine and Dental Health*

The Problem as It Relates to the Water Works Engineer

RAYMOND J. FAUST, C.E.

Assistant Engineer, Michigan Department of Health, Lansing, Mich.

PROGRESS made in the investigation of the fluoride content of water supplies and its relation to dental decay is being followed with much interest by the water works profession since it appears probable that a whole new problem will be placed in their lap for solution. The problem, of course, concerns the reduction of dental decay by the application of sodium fluoride to fluorine deficient public water supplies, and concurrently the prevention of mottled enamel by the reduction of the fluoride content of those supplies that exceed the optimum amount.

The reduction of the fluoride content of a water supply to an optimum amount may be difficult and expensive. To my knowledge there are no public water supplies in the country now being treated for the reduction of fluorides. In water softened with lime, a certain reduction in fluorides is reported by Scott, Kimberly, Van Horn, Ey, and Waring,¹ and Elvove² reports successful removal of fluorides in laboratory experiments with the use of calcined magnesite and light magnesium oxide. Removal of fluorides from potable water by tricalcium phosphate has been reported by Adler, Klein, and Lindsay.³ Wherever possible, the best solution to

the mottled enamel problem still appears to be the changing of the source of supply to one that contains 1 p.p.m. or less of fluorides.

The application of sodium fluoride to fluorine deficient public water supplies for the reduction of dental decay should not prove a difficult problem. Many supplies are now being treated for the reduction of hardness, clarification, taste and odor control, disinfection, corrosion control, color removal, stability, etc., so that chemical feeding equipment and control measures are well established and widely used. Also, much of the personnel responsible for water quality and treatment is highly trained. It is obvious, therefore, that should a program for applying fluorides be established, those supplies now receiving treatment under local laboratory control would have little difficulty in applying an additional chemical. Most of these supplies would need only additional chemical feed equipment to establish the treatment.

Fortunately, there are many types of good, inexpensive chemical feed equipment on the market. For the smaller supplies there are available several makes of pumps which are calibrated for output and which are usually powered with an electric motor, but which may be powered with a water motor or a gasoline engine. They may be operated manually or automatically.

* Presented before the Oral Health Group of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

The feed pumps are usually designed to apply the chemical solution to the water while it is being pumped, and at a place where the water is under pressure. This equipment is particularly suited to treat well water supplies, and especially those provided with deep well turbine pumps. The feed pumps are durable, accurate, and dependable. A single unit, which has a capacity adequate to treat a water supply with a daily average production of 1,000,000 gallons, costs installed approximately \$250 to \$350. One unit with a few spare parts should prove satisfactory with reasonable care for the treatment of a small supply for at least ten years.

Also available for the treatment of small supplies are gravity solution feeders which are adaptable for use where the point of chemical application is an open basin, such as at the inlet of a reservoir or to a pump suction. This equipment is accurate and equally inexpensive.

For the treatment of the larger supplies, equipment of the dry feed type is available and desirable. A choice between volumetric and gravimetric methods of measurement is also available. Dry feed equipment has been in service for many years, and is known to be dependable and accurate. Both small and large feeding equipment have an average accuracy within 5 per cent, which is greater than the accuracy of the test for fluorine in water.

The control of the application of sodium fluoride should not be confined to the accuracy of the feeding equipment, but should be dependent on the results of a test for fluorine in the treated water. Such a test should be simple in procedure, accurate to 0.1 p.p.m. of fluorine, and expeditious in results. A colorimetric test is needed with permanent standards that can be used by water plant operators having little or no technical education. A test kit similar to that used for determining

residual chlorine would be desirable. Present test procedure as outlined in *Standard Methods of Water Analysis, Eighth Edition*, uses temporary color standards and requires 18 hours for the completion of the test. This test would, therefore, be unsuited for general application.

Until a new and simplified test with permanent color standards is available, the application of sodium fluoride to public water supplies should logically be limited to those supplies having local laboratory control by technically trained personnel.

It has been my experience with water supplies in Michigan that many of them contain small amounts of fluoride (F), usually varying from 0.1 to 0.5 p.p.m., and in a few cases, slightly higher amounts. Obviously if a water supply were to be treated with sodium fluoride to 1 p.p.m. or any other predetermined amount, the natural or residual amount in the untreated water must be known and taken into consideration when computing the chemical application. It is apparent, therefore, that before the fluoride treatment is established on any supply, one or more analyses for fluorine in the untreated water are essential. Otherwise there would be an excellent opportunity to overtreat the water which may be sufficient to cause mottled enamel.

An attractive feature of the fluoride treatment of water supplies is its small cost, which is partly due to the application of only 1 p.p.m., and partly to the low cost of sodium fluoride which is quoted at 7 cents per lb. Since commercial sodium fluoride is 90 per cent pure, an application of 1 p.p.m. of fluoride (F) would require 20.5 lb. for each million gallons of water treated. Applying these figures to a town with a population of 7,500 and using an average of 1,000,000 gallons of water each day, the total cost for the fluoride treatment for a full year would approxi-

mate \$567. This figure includes the cost of the chemical, the chemical feeding equipment prorated over ten years, and the cost of a fluorine testing set, but does not include the cost of any labor, since no additional help would be required. On a per capita basis the annual cost of the treatment is about $7\frac{1}{2}$ cents, and for a family of four the annual cost would approximate 30 cents.

It is indicated in survey data presented by Dean, Arnold, and Elvove⁴ that the number of permanent teeth showing dental caries experience per 100 children examined, using water supplies with fluoride (F) concentrations between 1 and 1.4 p.p.m. was roughly 39 per cent of that found in children using water supplies containing fluoride (F) concentrations of less than 0.5 p.p.m. Likewise the findings for similar groups of children using water supplies containing fluoride (F) concentrations between 0.5 and 0.9 p.p.m. was roughly 54 per cent of that found in children using water supplies containing fluoride (F) concentrations of less than 0.5 p.p.m. From these data it could be concluded that approximately a 50 per cent reduction of dental caries in the permanent teeth of 12 to 14 year old white children is obtainable with the use of a water supply containing 1 p.p.m. of fluoride (F). This means that the annual dental bill for the restoration of decayed teeth in children of this age group can be cut in half. Of course, the fluoride treatment of water supplies means much more than this since all age groups will be benefited, but to what extent must first be determined before a complete cost analysis can be prepared.

Even though the benefits of the treatment are evident from a public health and a financial viewpoint, it is still prudent to consider the legal responsibilities that a town or private

utility accepts when it establishes the fluoride treatment of a public water supply. With that thought in mind, Dr. H. Allen Moyer, Commissioner, Michigan Department of Health, asked the Attorney General of Michigan for an opinion on the following question:

Could the owner (either a municipality or a private utility) of a public water supply be held liable for damages in the event that the supply was treated with fluorine and one or more customers developed mottled tooth enamel which they claimed disfigured their appearance or structurally weakened their teeth or made some similar complaint?

The Attorney General's opinion follows:

The general rule of liability as to private utilities in furnishing water for public domestic use has been summarized as follows: "A water supply corporation is not an insurer of the purity of the water furnished by it for public consumption, or of its freedom from infection, but is bound to use reasonable care and diligence in producing pure and wholesome water that is at all times free from any infection or contamination which renders the water unsafe and dangerous to individuals, or unsuitable for domestic purposes, and is liable for injury resulting from its failure to do so."

The same rule is generally held applicable to municipal corporations.

Before liability could be established it would be necessary that the plaintiff show negligence on the part of the utility or municipality furnishing the water and show that his injuries resulted from such negligence.

However, it is possible that liability could be established were it shown that through some negligence in treatment quantities in excess of one part per million were introduced from which damage resulted.

This opinion restates the responsibilities for which a water utility has always been accountable. In other words, the addition of fluoride to a supply does not increase or decrease those responsibilities. The opinion also emphasizes the need for a standard procedure for the control of the application of fluoride.

A request for an opinion on the following question was also made:

Assuming that the treatment was originally started for the benefit of the public health and admitting that the treatment of a public water supply with fluorine is mass therapy, could a local citizen who objected to the practice of treatment from a personal angle, but whose teeth were not damaged by the treatment, stop such treatment of the water supply?

In reply to this question the Attorney General's opinion was:

Assuming the authority of a municipality to add fluorine to its public water supplies, there would be no method by which a citizen not injured by but not sympathetic to the program could enjoin such treatment.

Finally, I believe it imperative that should the fluoride treatment of public water supplies be adopted that the state health departments should exercise supervisory control over the treatment in much the same manner now used in respect to the other types of treatment. Such control should include as a minimum, an annual inspection of all treatment plants by an engineer of the department, the submission of monthly reports on the operation of the water treatment plants to the health department, and, finally, and most important in my opinion, the establishment of a certification or licensing system which would insure competent and trained personnel to be in charge and responsible for the treatment wherever it is practised.

SUMMARY

The reduction of fluoride in a supply to an optimum amount for the preven-

tion of mottled enamel may be difficult and expensive. Changing the source of water supply to one containing less fluoride still appears to be good practice.

Adding fluoride to fluorine deficient water supplies for the reduction of dental decay should not prove a difficult problem, since accurate, durable, and inexpensive chemical feed equipment is available. The supplies that are now under local laboratory control with technically trained personnel could institute the fluoride treatment with very little new equipment. A quick, accurate, and simple test for fluoride (F) having permanent color standards is needed, however, before the treatment should be approved for general application. The cost of the treatment is small, averaging about 7½ cents per person a year. Legally, the responsibility of a water utility applying fluoride to a supply remains unchanged. Negligence in treatment which results in damage must be shown to establish liability. Supervisory control of the treatment by state health departments is desirable.

Meningococcal Carrier Studies*†

JOHN J. PHAIR, M.D., F.A.P.H.A., EMANUEL B. SCHOENBACH, CAPT., M.C., AUS, AND CHARLOTTE M. ROOT

*Department of Epidemiology, School of Hygiene and Public Health,
The Johns Hopkins University, Baltimore, Md.*

THERE has been a marked increase in the incidence of meningococcal meningitis throughout the United States during the past two years. Morbidity reports indicate that the number of cases during 1942 was twice the 5 year median 1937-1941. For the first 30 weeks in 1943 its prevalence was about seven times the 5 year median 1938-1942 for the same period, and surpassed the number reported for the year 1929.¹⁻⁴ This increase in the number of cases at a time of national military and industrial mobilization has served to focus the attention of those concerned with the investigation and prevention of epidemic disease.

The mode of dissemination of cerebrospinal meningitis has been repeatedly investigated and reviewed.⁵⁻¹¹ The importance of the meningococcal carrier has been considered in all reports, although a direct correlation of carrier percentage to case incidence has been difficult to establish.¹⁰ A carrier may be defined as an apparently healthy individual from whom the specific organism of a disease can be isolated.

The intricacy of the problem is greatly augmented by the fact that no adequate means are available to assess the virulence of the causative organism or the protective responses of the host. Resort to the antigenic differentiation of meningococci, and their subdivision into specific groups as isolated from cases and carriers, has been a distinct aid epidemiologically. At present it is assumed, with many reservations, that those types isolated from cases are virulent.

The present survey was planned to investigate the nature of the meningococcal carrier state in respect to duration, intermittency, frequency, and specific types of organisms prevailing. In addition the influence of the administration of sulfonamides on the carrier state was observed¹²⁻¹⁵ in the hope that an adequate and feasible means of controlling the carrier would result. The technics now available for culturing and typing the meningococcus furnish more complete data than those previously obtained.

SELECTION OF STUDY GROUPS

A medical service unit at a nearby Army camp was chosen. The group was fairly stable and had not been materially affected by large numbers of new arrivals or departures. No cases of meningitis had occurred in this detachment, minimizing the inclusion of

* Presented at a Joint Session of the Epidemiology and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

† These investigations were aided through the Commission on Meningococcal Meningitis, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Division, Office of the Surgeon General, United States Army.

"contact carriers" in the survey. The men in their duties formed a suitable sample of the camp as a whole. Some worked in offices as clerks, others were in the field as engineers and inspectors, while the remainder were assigned to special duties or served as ward men on the medical and surgical ward services. The medical ward men were not necessarily exposed to infectious diseases. A careful anamnesis was made of each individual, and all relevant data were assembled. Exposure to known cases of meningitis, medical past history, and recent sulfonamide therapy were specifically included. A record was also kept of the daily climatic variations and incidence of contagious disease at the camp for possible correlation with the rise and fall in carrier rate.

A group of 200 men were originally assigned to the study. One-half, selected at random, was chosen to act as a control (Group "B") and to serve

for study of the carrier state. The other half (Group "A") was cultured for a period of 1 week, and then 1 gm. of sulfadiazine was administered twice daily for 3 days to each man. About 1 month later this drug treated group was released and replaced by 110 new men, from the same service unit, for evaluation of smaller dosages (1 and 2 gm.) of sulfadiazine (Groups "C" and "D"). The original control group "B" was retained, except that during the last week of the study one-half of these men received 1 gm. of sulfamerazine. They were all cultured three times weekly throughout the period of the survey (Chart I).

CULTURAL TECHNIC

Nasopharyngeal swabs were inoculated directly upon warm 5 per cent rabbit blood agar plates containing para-aminobenzoic acid 5 mg. per cent. These were then carefully streaked and incubated under 6 per cent carbon

dioxide. Only type specific strains as revealed by agglutination in monovalent chicken sera¹⁶ (Group I, Type IIa and Group II) are reported. Previous experience with over 1,000 cases of meningitis had shown that the type distribution of strains was: Group I, 92.9 per cent, Group II, 1.1 per cent, Type IIa, 5.8 per cent, Group IV, 0.0 per cent, Gonococcus, 0.1 per cent, and non-typable meningococci 0.1 per cent. Thus, only Group I, Type IIa, and Group II carriers were of epidemiologic importance. All cultures were taken by one member of the Meningitis Commission. Inspection of the plates, subculture, and agglutination were performed by members of the Commission, all of whom had long experience in the cultivation of the meningococcus.

A system of quantitative assay was adopted with due realization of the many inherent fallacies. All plates having up to five colonies were graded as 1 plus, and only a single colony was chosen for subculture and subsequent agglutination. If the colonies were dissimilar in appearance then one of each type was chosen. All cultures graded as 2 plus to 4 plus (more than 5 colonies to a pure culture of meningococci) had at least two separate colonies chosen for typing. If there were dissimilar colonies each of these was also picked. In this way false negatives

were minimized and double infections frequently revealed.

Blood sulfonamide levels were made in all instances. A complete hematologic examination was performed on all those men receiving the drug for more than a single dose.

RESULTS

The results obtained may be presented in two parts. The studies on the carrier state comprise the first part and the changes in carrier percentage following the administration of the sulfonamide drugs the second.

The control group "B" was cultured at intervals of 2-3 days for a period of 68 days. Twenty-eight series of cultures were taken and each individual was cultured an average of 25 times. The results are summarized in Table 1. The total number of positive cultures was 1,030, or 41 per cent of all cultures made. Of these, 373 (14.8 per cent) were Group I; 240 (9.5 per cent) Type IIa; and 405 (16.2 per cent) Group II. There were twelve occasions in which agglutination occurred in both Type IIa and Group II sera and these have been recorded as Type II-IIa. The exact significance of this cross has not yet been evaluated as no absorptions were performed. All men carrying this type subsequently were found to carry a definite Type IIa or Group II.

TABLE 1
Carrier Survey, Control Group "B"
(99 individuals)

Result of Cultures	Total	Per cent Total Cultures	No. of Men Positive	Average Times Each Positive	Per cent Group B Positive
Positive cultures	1,030	41.0	91	11.1	91.0
Group I	373	14.8	54	7.0	54.5
Type IIa	240	9.5	38	6.3	38.3
Group II	405	16.2	50	8.1	50.5
Type II-IIa	12	.5	6	2.0	6.0
Group I & Group II	26	...	20	...	20.2
Group I & Type IIa	12	...	11	...	11.1
Group II and Type IIa	25	...	15	...	15.0
Group II and Type II-IIa	6	...	3	...	3.0
Group I, Type IIa, Group II	9	...	9	...	9.1

The number of individuals found to harbor the meningococcus was quite impressive. Ninety-one men of a total of 99 (91 per cent) were carriers at some time during the study, and each carrier was positive on an average number of 11 cultures. Fifty-four per cent of the men were found to carry Group I, 38.3 per cent Type IIa, and 50 per cent Group II meningococci.

No example of multiple nasopharyngeal infection with the meningococcus has been recorded in the numerous carrier studies reviewed. The stability as to type of the meningococcal carrier has been stressed.^{17, 7a} In this survey, however, 20.2 per cent of the men carried both Group I and Group II, 11.1 per cent carried Group I and Type IIa, and 15 per cent carried Group II and Type IIa meningococci. From 9.1 per cent of the men all three types (Group I, Type IIa and Group II) of meningococci were isolated during the 10 week period of study. This may have re-

sulted from the system of multiple selection of colonies for subsequent agglutination employed. It may also indicate the rapid exchange of nasopharyngeal flora among the individuals of the group.

The detailed results in Group "B" of each series of cultures are presented in Charts II and III. The carrier rates were persistently high except for a 2 week period when they fell to a much lower level. The men whose results contributed to these averages were not always the same. A dynamic equilibrium appeared to be maintained by the group as a unit. The static concept of a number of fixed meningococcal carriers circulating within a group could not be substantiated.

The oral administration of sulfadiazine in varying dosage resulted in a marked depression in the carrier rates. Those (Group "A") who received sulfadiazine, 1 gm. twice a day for 3 days, exhibited a prompt fall in the

CHART II

CHART III

carrier rate to 3 per cent on the 2nd day, which reached 1 per cent 3 days after completion of the course of drug. Carrier percentages preceding the ingestion of sulfadiazine had been 35.4, 39.8, and 44.8 per cent. The Control Group "B" had yielded concomitant carrier rates of 39.4, 40.4, and 43.8 per cent before and 47.2, 51.1, 50.5 and 55.3 per cent, etc., during the period after drug. The lowered carrier rates among those receiving sulfadiazine were maintained for the 3 weeks they were followed. A slight rise to 9.9 per cent was observed 2 weeks after the sulfadiazine administration had been terminated. The latter were chiefly Group I carriers and a similar rise in this group was present among the Control Group "B."

No drug reactions were noted with this dosage of sulfadiazine. The average blood level on the 3rd day, when 4 gm. had been ingested, was 3.6 mg. per cent.

The Groups ("C" and "D") that received a single 1 and 2 gm. administration of sulfadiazine also showed a marked fall in the carrier rate, from 36

and 25 per cent to 8 and 0 per cent, respectively. The group that received a single gram dose, however, began to exhibit a rise in the carrier rate soon thereafter. Sixty-nine per cent of those carriers detected after 1 gm. of drug therapy still carried the same type of meningococcus as had been previously isolated, and the interval between positive cultures was 11.1 days. The average blood levels of drug obtained 4 hours after administration of 1 and 2 gm. of sulfadiazine were 2.9 mg. per cent and 4.4 mg. per cent. Two gm. of sulfadiazine were apparently sufficient to eradicate the meningococcus from carriers as only 33 per cent of those found positive during the 3 week post-drug period carried the same type of meningococcus, and the average interval between positive cultures was 19.2 days.

One gm. of sulfamerazine (2-sulfanilamido-4-methylpyrimidine) was given to half of Group "B" during the last week of the study. The effect upon the carrier rate was quite similar to that following a single gram of sulfadiazine. The rate fell to 4.4 per cent within 2 days, from a previous level of 43 per cent, but had returned within a week to 20 per cent. The average blood level attained 4 hours after ingestion of the drug was 3.0 mg. per cent. Sixty-six per cent of the men who reappeared as carriers still harbored the original type of meningococcus, and the average interval between positive cultures was only 6.8 days. A comparison of the cultural results obtained with the sulfamerazine treated group and a concurrently cultured control group is presented in Chart IV.

DISCUSSION

From these briefly summarized studies it may readily be inferred that the carrier state is a complex dynamic equilibrium and not simply the presence of a few carriers in a group. The diffi-

culty of achieving adequate control through segregation or chemotherapy of known carriers is evident. The carriers detected at any one culture period form only a small segment of the true carrier population. Therapy must be directed at the group as a unit, and aimed at those factors that determine the group equilibrium.

The "carrier rate" is a complex term which has been widely employed because it is easily computed mathematically. The carrier percentage derived from any one culture series is only an index and does not represent the true carrier population or their biologic status. It is directly influenced by the nature and size of the group, the time selected for culture, the cultural technic used, the frequency with which the same individuals are cultured, the refinements of identification employed, and a host of similar factors. These components, of prime importance, are often not visualized in the final representation of a numerical percentage.

The apparent discrepancy of various cultural surveys probably results from the interplay of those factors enumerated. Comparison of the results obtained in this study with those of others can be made only if this concept is appreciated. In this presentation of the carrier state the same group was repeatedly cultured for approximately 10 weeks. Multiple colonies from each individual were chosen for agglutination in type specific chicken sera. The cultures were taken during a period when meningococcal infection was prevalent, although no case had occurred in this group of men.

The administration of sulfadiazine in relatively small dosage resulted in a marked fall in the carrier percentage. This method of carrier control may be feasible in certain situations of forced overcrowding or epidemic prevalence among selected groups. Care must be exercised in the prophylactic employ-

ment of the sulfonamides, as its widespread and injudicious use might, in turn, lead to the vexing problem of wholesale drug sensitization or possible infections with sulfonamide resistant meningococci.

SUMMARY

1. A carrier survey is presented in which a group was cultured at frequent intervals for 10 weeks. Ninety-one per cent of the men were found to harbor a type specific meningococcus. The average carrier percentage was 41.0 per cent. More than 50 per cent of the individuals were found to carry two or more specific meningococcal strains.

2. The effects of varying amounts of sulfadiazine and sulfamerazine on the carrier rate are presented. These rates may fall to zero levels after the administration of as little as a single 2 gm. dose of sulfadiazine. The low carrier rate thus obtained persists far beyond the period required for complete drug excretion. Sulfamerazine was no more effective than a similar amount of sulfadiazine in this study.

3. The possible use of the sulfonamide drugs as a prophylactic measure to halt the spread of cerebrospinal fever among selected groups is suggested.

ACKNOWLEDGMENT—This investigation received most valuable support through the generous coöperation of Colonel Thomas Burnett, Surgeon, Third Service Command, Colonel Harry H. Towler, Post Surgeon, Fort George G. Meade, and his Staff, Major Morris L. Grover, Major Roger D. Reid, and Major Richard J. Bruce. Acknowledgment of great indebtedness is made to those men of the Medical Detachment, 1322 Service Unit, Fort George G. Meade, who so wholeheartedly served in this study.

Meeting the Public Health Engineering Problems of the Army Overseas*

W. A. HARDENBERGH, COLONEL, SN.C.

Chief, Sanitary Engineering Branch, Preventive Medicine Division, Office of The Surgeon General, U. S. Army, Washington, D. C.

THE problems of sanitary and public health engineering with the Army overseas are both administrative and technical. The administrative problems include the determination of the positions where engineers are needed and how they may be used within the framework of the Army in a manner to contribute to its military effectiveness. Another, and not the least, problem has been to organize and graft onto the rapidly expanding Army a sanitary engineering service which, in times of peace it had not seriously needed, and to integrate this engineering service with the Army's program of preventive medicine. The number of engineers and entomologists in the peacetime Sanitary Corps has been greatly increased. There are now more than $6\frac{1}{2}$ times as many sanitary engineers and 15 times as many entomologists on duty as there were in 1941, and these must be increased by about 40 per cent during the next few months. Very few of our engineers had any previous training or experience in what may be called tropical sanitary engineering, and it has been necessary to provide this training, and to supplement it at times by

teaming together our engineers and entomologists.

From both the administrative and the technical viewpoints, the control of malaria is the most important overseas problem of preventive medicine. To date, malaria has been responsible for more hospital admissions than has the Japanese Army. The administrative problem is to organize and provide personnel properly trained and equipped to combat malaria all the way from rear areas to the fox holes of the front lines. The technical problems of control are no less difficult for the men charged with putting this program into effect. To us in this country, the prevalence of malaria in the Southwest Pacific and in certain parts of Africa and Asia is almost unbelievable. Practically every native is infected. To make the problem more difficult, rainfall is very heavy—up to 250 inches per year in some areas—and anopheles mosquitoes breed in every puddle or, as Captain David B. Lee says, "wherever there are two teaspoons of water." Breeding has even been found in the folds of tarpaulins placed over piles of supplies.

Dysentery is second in importance to malaria as a cause of hospital admissions but falls far behind on the basis of noneffectiveness. Where recovery from malaria is a matter of months,

* Presented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

dysentery incapacitates for only a few days, as a rule. Other diseases are generally far less important but consideration must be given, from the engineering viewpoint, to various insect-borne and intestinal diseases including dengue, amebic dysentery, and possibly schistosomiasis.

The control of these diseases can be accomplished only by a broad program of preventive medicine, in which sanitary engineering has a most significant part. A necessary preliminary is the establishment and maintenance of sanitary discipline, that is, teaching the soldiers how to protect themselves against disease. This program utilizes specially made moving pictures and supplements these with lectures, booklets, demonstrations, and field instruction. Stress is laid on purification of water; protection and handling of food; safe waste disposal; cleanliness of kitchen and mess utensils; the use of mosquito repellents, sprays, and nets; the value of clothing as a protection against mosquitoes; and the necessity for the regular use of atabrin. This training and instruction aim to make the performance of these safeguards as routine and automatic as the movements in drill. Sanitary engineers and entomologists aid in this instruction and they supervised the preparation of the films on malaria control, field water supplies, and human waste disposal.

The control of malaria in the field requires the coordinated effort of all officers and men, and of all ranks and services. Therefore control may begin in the infantry company with the designation of a non-medical malaria unit consisting of one non-commissioned officer and one enlisted man, working under the direction of a battalion non-medical malaria officer. The duties of this unit may include responsibility that every man in the company has and uses repellents; that "water tidiness" is observed in the company area and all

casual water is oiled; that soldiers use mosquito nets properly and keep them in repair; and that supplies of repellents and sprays are available. This company organization can do much to carry effective control into the very front lines by sending forward repellents, sprays, and atabrin; and by continued education and training of the unit to which they belong.

In areas farther back are Medical Department Malaria Control and Malaria Survey Units, of which a large number have been organized and are now serving on every overseas continent. A Survey Unit consists of one entomologist, one parasitologist, and eleven enlisted men, with necessary transportation and laboratory equipment. Its function is to determine the local conditions affecting malaria control, including the types and prevalence of mosquitoes likely to transmit the disease. A Malaria Control Unit consists of one sanitary engineer and eleven enlisted men, with transportation. Its function is to carry on control work—oiling, ditching, etc.—mainly with local hired labor, for which purpose it is equipped with a supply of tools, oilers, and dusters. While not normally intended to operate in forward areas, at least one of these units was engaged in control work within a mile of the battle lines in Sicily. Both the Control and Survey Units are under the direction of the Surgeon through one or more of the malariologists on his staff.

Experience has shown the need for specially trained troop units to carry on work in actual battle areas. Therefore to round out the malaria control program, arrangements are now under way to organize, equip, and train Malaria Control Companies of about 50 men, generally similar in organization and function to the Anti-Malaria Company of the Navy Construction Battalion. These may have some heavy equipment such as a bulldozer and a

small dragline, and plenty of small tools. They should initiate anti-larval work promptly around all areas that are to be held permanently. Screening of buildings at the earliest possible moment is highly desirable, especially mess-halls, recreation buildings, and other places where men gather. Native villages that are located within about 2 miles of areas to be occupied more or less permanently by troops should be moved, as they provide a most important focus of infection. In this connection, natives should generally be prohibited from visiting the camp between sunset and sunrise. Prevention of man-made malaria mosquito breeding places is another function of these anti-malaria units.

In addition to these special malaria control organizations, sanitary engineers are assigned to Armies or other troop echelons to advise on water treatment methods for the removal of ameba cysts, the cercariae causing schistosomiasis, warfare gases, fish oil, and various toxic contaminants; on the selection of camp sites of a fairly permanent nature, where consideration must be given to the quality and quantity of water supply; the methods of waste disposal; the proximity of native villages and mosquito producing areas; and the sanitary condition of the areas adjoining the site. As in this country, it is easier and better to discover and correct sanitary defects before the troops move into an area than to attempt to remedy them after the camp is established. The maintenance of sanitary discipline by frequent inspections is of great importance. In all of this work, the engineer is under the direction of the Surgeon of the Command.

Overseas, as in this country, there are many service and area installations such as air bases, supply depots, hospitals and training and rest areas. A sanitary engineering service, generally similar to that provided for camps,

posts, and stations in this country, is necessary for these installations. Work may include mosquito and other insect control, and supervision of water supplies and waste disposal facilities.

For service with the Military Government Division, 50 sanitary engineers and 25 entomologists have been assigned to the Provost Marshal General and more engineers have been informally requested. These officers will normally serve with the Public Health Section of the Military Governor's Staff. They will not act as the operating health department personnel in occupied foreign countries but will supervise the activities of native officials working under allied military control. They may, however, be required to advise on the repair and reconstruction, as well as the safe operation, of water supply and waste disposal systems.

Thirty-five engineers of the Sanitary Corps are on duty with the Coordinator of Inter-American Affairs in South and Central America. They are initiating and carrying out a broad program of environmental sanitation and public health, including projects for malaria control and the design and construction of water and sewerage systems. In connection with the development of the rubber resources of the Amazon, jungle bases have to be established, hundreds of miles from civilization, and necessary sanitary engineering works constructed to make these bases habitable. Each engineer is largely on his own, and he has been obliged to draw heavily on his resources of skill, knowledge, and adaptability.

All of the Sanitary Corps officers assigned to these and other overseas duties have been obtained from civilian life, or from the Army shortly after induction or enlistment. Few of them had any previous experience in foreign countries, and almost none in the areas in which our armies are operating. Instruction in what may be called tropical

sanitary engineering seems to have been wholly overlooked in most of our colleges and universities. As a result of all these factors, it was considered necessary to train our officers, not only in Army methods and routine but also in various phases of sanitary engineering in which they had not had previous experience.

As soon as an officer is commissioned he is ordered to a 4 to 6 week refresher course at one of the Medical Department Schools. This orients him in the general performance of his duties and instructs him in the elements of drill and the customs of the Army. Upon completion of this course, he is normally ordered to a post in this country where, through actual service, he improves his Army education and learns the channels and the methods through which results are accomplished. A number of special schools, such as malaria control and tropical medicine, are available to which he may be sent during this period. So far as possible, officers are given at least 6 months of experience prior to foreign assignments. However, due to heavy demands for personnel for overseas service, it has not been possible in all cases to adhere to this schedule. We have frequently been short of personnel because we have

had to fill all our foreign duty requests, while maintaining our operating and training organization in this country.

So wide is the scope of overseas work in which Sanitary Corps engineers are engaged that it is obviously impossible to train them specifically for all the jobs they may encounter. Fortunately, this has not been necessary, for their basic training and experience have normally been such as to enable them to find satisfactory answers to most of the questions that arise. Because of the variety of problems that may and do arise, it is difficult to give here more than a brief outline of their duties. In planning for their utilization overseas, special efforts have been made to insure that, so far as possible, these officers are employed on sanitary engineering work and that they operate under a clear-cut authority, which permits them to concentrate on the job before them. Our sanitary engineers are serving on every continent and at every front. I am looking forward to the time when they will be back here to attend these meetings, and I hope there will be an opportunity then for them to tell personally of their work, for their experiences should prove most interesting and valuable to us all.

Present Status of Gonorrhea Control*

NELS A. NELSON, M.D., M.P.H., F.A.P.H.A.

Associate in Venereal Diseases, The Johns Hopkins University, School of Hygiene and Public Health, Baltimore, Md.

IT should be a matter of grave concern to all of us that the gonococcus does not read the *Reader's Digest*, for I might otherwise have been able to report, simply, that a handful of "soda-mint" sulfathiazole tablets has the situation well in hand and, thereupon, to the relief of all of us, have sat myself down. Perhaps we should do well to interest this ignorant organism in that estimable journal in anticipation of the article on penicillin in the control of gonococcal infection which is bound, sooner or later, to appear. In the meantime, however, there remain some problems which, lacking solution continue to interfere with the control of gonorrhea, and the discussion of which will occupy us here.

Because we are better off therapeutically than in all other categories, I shall reverse the logical procedure and discuss therapy first, leaving diagnosis and epidemiology for consideration, in that order, a little later on.

Early in 1937 sulfanilamide was introduced to the American scene by Dees and Colston¹ as a speedy cure for gonorrhea. The effect was explosive, for in spite of the badly needed overhauling which had been given by Pelouze to the older forms of treatment, they still left too much to be desired. Although calm review now reveals that most of the early reporters of the effect

of sulfanilamide on gonorrhea used the best criteria of cure which were then generally available, and admitted many failures, it had become the universal opinion by the end of that same year that the control of gonorrhea was just around the corner and, as reported by *Time*, for something like 40 cents.

By the middle of 1938, however, the American Neisserian Medical Society had reported² that "The drug sulfanilamide is still under investigation . . . and no recommendations relative to its use are therefore made, but to those who are to use it experimentally, the following precautions are advised: Patients . . . should be observed for at least 3 months following apparent cure. In the advent of failure to observe clinical response within 5 days, it is wise to discontinue the use of the drug."

Fortunately, as other sulfonamides began to appear, culture of the gonococcus was not only improved, but more widely used in the evaluation of the efficiency of these new drugs. In 1939, the aforementioned Society declared³ that "No claim for cure, from any source, should be given serious consideration unless supported by thorough cultural study."

In 1942, this same group of experts advised⁴ that "Sulfanilamide should not be used for the treatment of gonorrhea because much more efficacious drugs are available." In the short span of 5 years, the star of sulfanilamide had reached its dizzy zenith and had set. It is known today that this drug does not cure more than 30 per cent of

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

gonococcal infections, and that a dangerously high proportion of the uncured patients remain asymptomatic carriers of infection for months.

Thanks to the lessons we have learned, and excepting the *Reader's Digest*, we have not been so completely over-optimistic about the newer sulfonamides. We are quite calmly aware that the most effective of them, sulfathiazole, sulfadiazine and sulfamerizine, cure not over 70 per cent of gonococcal infections within 2 weeks, under rigid criteria of cure and the adequate elimination of the element of time as a function of cure by itself.

In spite of many attempts to speed the cure and to reduce the number of failures by the administration of larger doses or of longer courses, the consensus still is that a treatment schedule of 4 grams a day for 5 days combines the greatest degree of safety with a maximum rate of cure. That there may be scientific evidence that this rate of cure cannot be exceeded for these drugs, no matter how they are administered, will be discussed a little later on.

Compared with the results obtained with pre-sulfonamide therapy, however, this degree of success is nothing short of miraculous. The sulfonamides, moreover, have made the treatment of gonorrhea a function of general medicine, and there is hope that the general practitioner may become far more interested and expert in their proper use than the urologist and the gynecologist ever were in irrigations, injections, prostatic massage, and douches of this and that. The manner in which they prevent complications, which so often require surgical intervention, would alone warrant their routine use.

Nevertheless, both the clinician and the health officer must be concerned with the too high proportion of failures, for the sulfonamide resistant strains may take over, in our promiscuous population, when the others have been ex-

terminated and leave us as badly off as we were before. They are rapidly becoming a real problem in clinics, to which the uncured are drifting in larger and larger numbers from the offices of private practitioners. It is even becoming difficult to evaluate new drugs because so large a proportion of the infections of research clinic patients are now sulfonamide resistant.

Until penicillin appeared upon the scene, it seemed that fever therapy offered the only alternative to a return to the older and unsatisfactory methods of treatment for the sulfonamide resistant infection. It is doubtful whether any considerable number of physicians, even in our clinics, would be persuaded to use irrigations, injections, or prostatic massage, or could be taught to use them properly. They had not been so persuaded or taught during the many years prior to the appearance of the new drugs. The treatment of gonococcal infections in women by douche, suppository, and topical application is little more than a combination of uncertain hygiene and unsound medicine.

Fever therapy, on the other hand, involves certain serious risks and requires the hospitalization of the patient under the care of highly trained medical and nursing personnel. It could not be made generally available for years to come, even in those areas where hospital facilities exist at all, and its use on any form of mass basis is almost out of the question.

Little has been published to date upon the effect of penicillin upon gonococcal infection, but a considerable investigation of this new drug is going on within the limits of its availability. The results so far reported are almost too favorable, but the investigators are showing commendable restraint in their interpretation of those results in their application to the whole problem of gonorrhea. Most of the work, so far, has been done with sulfonamide re-

sistant infections, and there remains much more to be done before it is determined what the minimal effective dose may be, and how it may best be administered.

An interesting but as yet incomplete and unpublished investigation is under way at the Harvard Medical School and the Boston Dispensary which may solve the whole question of what drug to use, and do away, as well, with the difficult problem of case control. It appears that it may be possible to determine by cultural procedures within a matter of 24 to 48 hours whether a given infection will ever respond to sulfonamide therapy. If this proves to be so, a patient may be seen today and a specimen obtained for culture. Sulfonamide therapy may be started at once, to gain the advantage of prompt treatment for those infections which are to respond, and the patient directed to return in 48 hours. If cultural study discloses that the particular strain of gonococcus with which the patient is infected is sulfonamide resistant, the drug may be discontinued and penicillin administered without further delay. Those infections which it has been determined will respond to sulfonamide may be continued on the drug with the knowledge that they will be cured by a single 5 day course of treatment. Those treated with penicillin will also be cured by the single course of therapy. It will make little difference, outside research clinics, whether the patients ever return for post-treatment observation.

It may prove, of course, that penicillin will cure practically all gonococcal infection. If it can be synthesized and made readily and cheaply available, and if the treatment time can be so shortened that all patients will accept it, the problem of therapy will be solved.

Therapeutically, therefore, the possibility of controlling gonococcal infection looks brighter than ever before, although it is much too early to toss

our hats into the air. (I hope that no representative of the press is in the room who lacks even greater restraint, for as we shall see, there are other conditions to the control of gonorrhea than the perfection of its therapy.)

THE DIFFICULTIES OF DIAGNOSIS

One stumbling block to the extermination of the gonococcus, however efficient the therapeutic armamentarium, is the difficulty of diagnosis. There is no procedure for the detection of infection with this disease which can be applied on a routine or mass basis, as the blood test for syphilis for instance may be. Search for infection begins ordinarily only when a person with clinically manifest disease presents himself for medical advice, or epidemiologic investigation has produced alleged contacts for examination. In women, the signs and symptoms of gonorrhea are often so mild that medical attention is not sought, or so confused with the signs and symptoms of other common genitourinary conditions that the physician never thinks of looking for the gonococcus. Innumerable males still treat themselves, or pay little attention to their infections beyond cursing them as temporary inconveniences and annoyances. This is especially true of Negro males. The best of treatments can have no effect upon those infections which do not come to medical care.

Unfortunately, however, diagnosis is not a simple matter when the patient does present himself for examination. Smears stained by the method of Gram are usually as efficient as cultures for the detection of the gonococcus in males with fresh infections. As the symptoms subside, smears become less and less useful until, in asymptomatic prostatic infections, they may fail to confirm a diagnosis in 80 to 90 per cent of the cases. If the patient has already taken any of the sulfonamide drugs (which many have when they first re-

port for medical attention) the value of smear examination may be quite problematical.

In fresh acute infections in the adult female, repeated smear examination will often result in the detection of the organism, but the first smear, which in private practice is often also the last, will be negative in at least half the cases. With the passage of time even repeated smear examination will offer little hope for confirmation of the diagnosis, and errors may be made due to the presence of other members of the group of Gram-negative diplococci. In female children the presence of these other organisms is so common, and they so frequently cause clinical symptoms indistinguishable from gonococcal infection, that nothing less than cultural identification of the gonococcus can be depended upon to make the diagnosis of gonorrhea.

Culture of the gonococcus is still a procedure which calls for much training and experience. The experts do not yet agree upon which is the most satisfactory medium, and contamination and overgrowth by other organisms have not been adequately controlled. Unless a medium can be devised upon which the gonococcus can be made to grow with the greatest of ease by the average bacteriologist, it is unlikely that cultural service will become very rapidly available to the country at large.

This disadvantage may be partly overcome if present efforts to devise a medium in which the organism can be kept alive are successful, for it may then be possible to send specimens by mail to central laboratories where expert bacteriologists are available. Cox⁵ in particular at the Boston Dispensary has made considerable progress in the development of such a medium, although many kinks remain to be ironed out of the procedure. Phair,⁶ at The Johns Hopkins School of Hygiene and Public Health, has discovered that spe-

cific serum may be produced in chickens which may provide a more rapid and satisfactory method of distinguishing between the several Gram-negative diplococci than is possible by the currently used fermentation tests.

The lack of adequate cultural facilities for the detection of gonococcal infection has been keenly felt during the war emergency, since the armed forces have undertaken the identification of contacts of infected men. It is almost the rule that by the time the female contact can be located and examined, smears are of little use, and clinical examination produces only indeterminate results. This has led to the advice by many experts that if an alleged contact so much as admits sexual exposure outside of marriage, or has any symptom or sign which might indicate gonococcal infection, treatment as for gonorrhea should be given. The danger of toxic reaction is so slight when compared with the risk of continued spread of infection by an undetected case, or of pelvic extension in an untreated case, that this procedure is held to be quite justified.

If, however, we may be so rash as to assume that the therapeutic and diagnostic problems are on the way to solution, may we then assume that the control of gonococcal infection will be assured? That will depend, of course, upon what proportion of the total number of infections in existence at any given time are detected and cured before as many new infections can be caused to replace them. Since no one knows what the incidence of gonococcal infection in the civilian population may be, we can arrive at no approximation of the job in public education which lies ahead. One has only to note the casual manner in which urethral discharges are treated by most colored and many white males to suspect that this job of education will be a large one.

It would seem that it should be possible to teach males, if not to suspect

exposure in every promiscuous sexual relationship, to realize at once that any urethral discharge which appears soon after such a relationship is abnormal and most likely due to disease. This will involve the correction of the popular notion that strain can cause such a discharge. It will be difficult to convince most males that gonorrhea is actually a serious disease (which it is *not* in the great majority of infected males). If, however, it can be demonstrated that treatment of an annoying and embarrassing discharge is promptly effective, inexpensive, and less inconvenient than the condition itself, males may be persuaded to seek treatment for any urethral discharge without having first to be convinced that it is due to a gonococcal infection.

If the treatment is also sufficiently free from risk, it may be worth while to treat every urethritis first, and attempt a more specific diagnosis only if therapy fails. This might not be as outrageous as it sounds if we can be persuaded to accept urethritis as an adequate diagnosis, even for purposes of morbidity reporting, and forego the doubtful satisfaction of accumulating still more doubtful statistics on gonorrhea. If urethritis is eventually controlled, gonococcal infection is bound to disappear with it.

This brings us abruptly face to face with the question of epidemiology. It will be argued that unless the diagnosis of gonorrhea is made there will be no basis upon which contact tracing may be pursued.

It is true that it would be ridiculous to follow all of the sexual contacts of every woman with a leucorrhea, or who can be persuaded to admit sexual promiscuity. I doubt, however, whether the control of gonorrhea will derive from the detection and prompt treatment of infection in women. It will be impossible to educate the female to suspect infection through the separation of

the signs of gonorrhea from those of the many other genitourinary conditions to which she is heir. Physicians cannot do it without culture, or without good luck with smears. It is not easy to detect infection in the known female contacts of males with gonorrhea. I am not at all certain that we are not wasting our time with case finding. It is my opinion that if infection in most males could be detected and cured immediately after it became clinically evident, gonococcal infection in most females would soon disappear. It might be worth while to try the experiment of concentrating upon the control only of urethritis in the male, depending upon education, clinical diagnosis, and our excellent therapeutic armamentarium for its accomplishment.

Treatment, of course, is the application of a control measure after infection already has occurred. Ideally, disease is prevented. The control of gonorrhea by preventive measures can be accomplished only by one of two procedures, or a combination of them; namely, prophylaxis and the abandonment of sexual promiscuity.

The proponents of prophylaxis argue that there will never be any effective abandonment of promiscuity or, at any rate, that we cannot afford to wait for it. The proponents of the abandonment of sexual promiscuity argue, even more vigorously, that prophylaxis encourages promiscuity and will forever perpetuate it.

A truly effective and popular prophylactic would be an attractive and tempting solution of a great and serious public health problem. On the other hand, I am not convinced that the control of disease is the most important consideration among the many which revolve around the question of what to do about sexual promiscuity. We live in a civilization which, although notorious for its violation of them, is bound round with behavior codes. They have

not arisen out of the perverseness of human nature, but out of a fierce insistence that the integrity of the family, as the fundamental unit of our civilization, be preserved. I am not competent to referee the debate as to whether we have the right, for the immediate solution of our own problem, to ignore these other considerations, and I shall drop the subject at this point. As a reporter of what is going on in the field of gonorrhea control, however, I am obliged to pay attention to the fact of prophylaxis.

Whether the promiscuous members of the population can ever be persuaded to use prophylaxis regularly and intelligently is a moot question. Currently available prophylactics are unattractive and inconveniently used. They have never been popular, although there is wide knowledge of their availability. In the armed forces, where instruction is regularly given in their use and importance, and where they are all but forced upon the men, they are so inadequate to the control of infection that tremendous pressure is being put upon civilians to repress promiscuity in their communities.

The average male is not sufficiently impressed that there is any danger of infection in his sexual relationships with the "nice, clean girl" with whom he consorts, to be persuaded to use inconvenient and messy prophylactics. But if a prophylactic could be produced which could be popped into the mouth, in pill form, at the first, faint prickings of doubt, *after* intercourse, when the excitement of the chase had been succeeded by more cool and more sober reflection, prophylaxis might become popular in spite of all the arguments

for, or against. Research probably will not cease until it is found, but I shall offer no prediction as to what the subsequent moral upheaval will be.

The title of this paper is The Present Status of Gonorrhea Control. I can offer not the slightest information upon that point. The therapeutic armanentarium is excellent and is constantly being improved; we may hope for great improvement in diagnostic procedures; we should be able to do better than we have with public education, and someone is certain sooner or later to produce an effective and popular prophylactic. But there is no base line from which we can measure progress. We know next to nothing of the current incidence or prevalence of gonococcal infection. Our instruments of measurement are so crude that we cannot even detect wide fluctuations in these values. That, however, should not detain us, for if we make the fullest use of every facility at our disposal we may one day discover that no person can any longer be found who can produce a gonococcus. That day, the *Reader's Digest* will please note.

Plasma Reserves for Civilian Defense, Their Distribution, Control, Preparation and Clinical Use*

With Special Reference to the Treatment of Infectious Diseases

JOHN B. ALSEVER, M.D., SURGEON (R), U.S.P.H.S.

Chief, Blood Plasma Section, Office of Civilian Defense, Washington, D. C.

WHEN the United States was so treacherously attacked in the Pacific on December 7, 1941, the U. S. Office of Civilian Defense, realizing that further attacks could well be expected, accelerated the development of the various protective services which had been established earlier in the year. The Medical Division felt that adequate reserves of plasma were of vital necessity for the treatment of civilian casualties which might result from enemy attacks. The existing donor procurement program of the American Red Cross and the commercial laboratory facilities for the preparation of plasma were required for the expanding needs of the armed forces, so that we could not expect to obtain large amounts of plasma from this source. We, therefore, secured the coöperation of the Public Health Service in developing an independent program.

In April, 1942, \$292,500 was allocated to the U. S. Public Health Service for this purpose by the President from his Emergency Fund, and the program was continued during the fiscal year of 1943 with an additional Congressional appropriation of \$499,500. The language of the appropriations permitted

the procurement of plasma from commercial laboratories and the making of grants-in-aid to public and private hospitals to assist them in preparing local reserves of blood plasma. The program, therefore, has been supported by funds provided by the U. S. Public Health Service and administered by the Medical Division of the Office of Civilian Defense.

The grants-in-aid program for hospitals, which has been our chief activity, was conducted in accordance with regulations issued by the Surgeon General. It was felt that the establishment of hospital blood and plasma banks was consistent with good hospital practice and that they would be of real and lasting value to the community. To be eligible to receive a grant-in-aid, a hospital was required to have a bed capacity of at least 200, to be on the approved list of the American College of Surgeons and the Hospital Register of the American Medical Association, and to have, as director of the plasma project, a physician whose qualifications were the equivalent of those required by the American Board of Pathology for its diplomates. The hospital also agreed:

1. To build up a plasma reserve of at least one unit per bed within 3 months after delivery of the necessary equipment, except that hospitals which were located within 75 miles

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

of a Red Cross bleeding center were given a longer period of time to build up their reserves and were required not to engage in publicity campaigns for donor procurement. (A unit of plasma is defined as that amount obtained from 500 ml. of citrated blood, usually 300 ml.).

2. To maintain this plasma reserve for the duration of the war and release it for use without charge for the treatment of casualties caused by enemy action or sabotage on order of officers of the Emergency Medical Service.

3. To prepare plasma by one of the technics approved by the National Research Council.

4. To utilize the equipment to operate a blood and plasma bank for its own routine needs for the duration of the war. (The equipment now belongs to these hospitals and the plasma reserves will become their property at the end of the war.)

On June 30, 1943, when the appropriation terminated, grants had been made to 168 hospitals. Two state laboratories and one county laboratory received priority assistance in obtaining equipment. These institutions have pledged a total reserve of 78,790 units of plasma, of which 70 per cent has now been prepared. In addition, many other hospitals, operating blood and plasma banks independently of our program, have voluntarily placed their plasma reserves, which total 32,600 units, under the control of the Emergency Medical Service.

In the preparation of their plasma, the grantee hospitals have followed the technics set forth in the manuals, *A Technical Manual on Citrated Human Blood Plasma* and *A Technical Manual on the Preservation and Transfusion of Whole Human Blood*, prepared under the direction of the Subcommittee on Blood Substitutes of the National Research Council. These manuals discuss the operation of a hospital blood and plasma bank and describe several approved technics for the storage of whole blood and the preparation of plasma. All of these methods employ a "closed system," in which the entire procedure, from the collection of blood to the filling of a final container of plasma, is

carried out in such a manner that the blood and plasma are never exposed to anything but filtered air. The use of such a system makes contamination of plasma a rare occurrence.

Plasma may be prepared either by centrifugation of freshly collected blood or by gravity sedimentation of whole blood stored in a refrigerator. The use of a dextrose preservative solution is recommended if more than 5 day storage of whole blood is desired. Plasma is pooled in minimum amounts of 2,000 ml., unless 50 per cent dilute plasma is being prepared. The reserves of plasma are stored either in the liquid state at room temperature or frozen and kept at a low temperature. Almost all of the hospitals in this program have centrifuge equipment and low temperature storage cabinets. Many of them employ both methods of plasma preparation and both methods of storage.

Recent studies at both the Army and Navy Medical Schools have demonstrated that liquid plasma kept at room temperature has a safe storage period of 2 years. The temperature should be held between 60 and 80° F., with allowable maximum limits of 55 to 100° F. There is, of course, rapid loss of prothrombin and complement and a slow loss of antibody content with this form of storage, but these changes do not interfere with the value of the plasma in the treatment of shock. Plasma stored in the frozen state remains practically without change during storage. At +5 to -4° F., the official limit of storage is at present 3 years. I feel sure that this time limit is conservative. Actually, there seems to be every reason to believe that plasma can be stored indefinitely at this temperature range.

In addition to the grantee hospital program, it was felt to be necessary to obtain a supply of dried plasma. With the approval of the Surgeon General

of the Army and the coöperation of the Blood Donor Service of the American Red Cross, 37,500 units of dried plasma were obtained from the Hyland Laboratory in Los Angeles. In this area the Red Cross was able to recruit and bleed donors for us without interfering with its procurement for the armed forces. An additional 12,500 units of dried plasma were later obtained from the Army supply after the armed forces had accumulated a safe reserve. This gave us a total of 50,000 units. The Red Cross has provided an additional 5,000 which is available through its Disaster Relief Service.

In addition to the dried plasma, a third phase of the program was carried out in coöperation with the Army, Navy, and the American Red Cross. In order to afford immediate protection to those cities in which the Red Cross was operating donor centers, the Medical Division placed reserves of frozen plasma, obtained from commercial firms, in each of these cities during the summer and early fall of 1942. Arrangements for this were made with selected hospitals which were furnished with refrigerated storage units. Frozen plasma was used instead of the dried form because the commercial firms at that time had on hand more frozen plasma than they could dry, and the armed services needed only the dried plasma.

In all, 29,500 units of frozen plasma were distributed throughout the country. This plasma, as well as the 50,000 units of dried plasma previously referred to, was prepared from blood collected by the American Red Cross and obtained through government contracts with the various commercial laboratories by paying these firms the cost of processing.

In the selection and approval of the 168 grantee hospitals and in the distribution of the commercially prepared dried and frozen plasma, the first con-

sideration was to obtain a plasma reserve in each locality which was felt to be adequate in the light of local risk of enemy attack, sabotage, and industrial accidents. It was, of course, not possible to provide sufficient plasma in every community to meet the needs of all casualties which might result from a "blitz" type of disaster, but there is, generally speaking, an adequate amount locally available in every important community to handle any situation for a period of several hours. This provides time in which to send in any necessary additional supplies of plasma if the community is in danger of exhausting its own local supplies.

The dried plasma has been of inestimable value in enabling us to attain a more satisfactory distribution, because, unlike liquid or frozen plasma, it can be stored anywhere, providing the package is not allowed to freeze or is not exposed for long periods to temperatures above 130° F. It can, therefore, be transported with ease. Also, since it was obtained in the standard Army-Navy type package, each unit is complete with distilled water for reconstitution and an administration set, so that it can be used in the field without regard to hospital facilities. Dried plasma offers no advantage, however, for general hospital use. Therefore, we have utilized the dried plasma in two ways. First, relatively large depots of this plasma have been established in key cities where there are excellent transportation facilities. These depots constitute our primary mobile reserve which can be shipped to other communities to meet emergency needs. Second, it has been distributed, usually in small amounts, to provide enough plasma for the initial protection of small, relatively isolated communities.

For purposes of administration, the Office of Civilian Defense has divided the country into nine Regions which are coterminous with the Army Service

Command Areas. There is a field office for each Region which maintains direct contact with the states. The plasma reserves are controlled by the Civilian Defense Organization. The local Chief of Emergency Medical Service, whose authority covers one city or county, has control of the plasma available locally. If he should need an additional supply, he requests it from the State Chief of Emergency Medical Service, who has control of all the reserves stored within his state. In approximately half of the 48 states, the State Chief is also the State Health Officer. If the state's supply should be in danger of exhaustion, the State Chief can obtain more plasma from the Regional Medical Officer, who has control over all plasma reserves within his Region. In addition, the Regional Medical Officers may arrange for the movement of plasma from one Region to another.

We have been able to make very satisfactory arrangements for the shipment of plasma in an emergency. The Civil Air Patrol will fly plasma on request of the Regional Medical Officer whenever air transportation is necessary. The Railway Express Agency has agreed to accept an emergency shipment of plasma for the government if given only the serial number of the bill of lading which will later be issued to cover the shipment. This means that there need be no delay in the shipment of plasma by rail or air express. Most states have also made arrangements with the state police, highway patrol, or sheriffs, as the case may be, for auto transportation whenever that becomes necessary.

To summarize, there are at present available to the Emergency Medical Service more than 160,750 units of plasma stored in 675 storage depots in 382 cities in the United States, and there is no community in this country that does not have quick access to these

plasma reserves, should an emergency arise. Plasma reserves also have been provided through this program for Alaska and Puerto Rico, but not for Hawaii and the Canal Zone which have been under Army administration.

Today, there is no question of the tremendous value of plasma in saving the lives of persons who have been seriously injured, whether it be on the battle fronts or on the home front. It is now known that in all severe injuries there is a loss of circulating blood volume into the injured tissues as well as loss by hemorrhage. This causes the circulation to become inadequate, resulting in tissue anoxia and shock. The shock state may terminate in death if adequate treatment is not given promptly. If the blood volume is restored within a few hours after the injury and maintained at an adequate level, an individual can recover from very severe trauma. The special value of plasma is that, like whole blood, it restores blood volume physiologically, except for the red cells which may have been lost through bleeding. Unlike whole blood, it can be made available in large amounts, can be stored over long periods of time, and can be administered without reference to blood group, cross matching, or skin testing. Plasma, like whole blood, is far superior to salt solution, glucose, or acacia for treating shock.

It should be emphasized that plasma must not be considered to have completely replaced the use of whole blood in the treatment of shock. In fact, if it is immediately available, whole blood is preferable to plasma if the shock is due to hemorrhage. However, even in a case of severe hemorrhage, plasma in adequate amounts is life saving and should be used if whole blood is not immediately available, for this can always be given later on. A person cannot survive long without a blood volume large enough to maintain adequate cir-

culatation, but he can survive a severe degree of anemia.

Unfortunately, there is no rule or formula by which one can determine the amount of plasma necessary in a given case. The only safe and practical procedure is to give enough plasma to achieve the desired result; namely, restoration and maintenance of normal blood volume. Time does not allow for a detailed discussion of dosage, except to say that a severely burned person may require 3 to 6 liters of undiluted plasma in the first 72 hours and that at least 1 to 1.5 liters are required in cases of severe injury.

Since April, 1942, when the Public Health Service began this plasma program, over 5,000 units of plasma have been used by the grantee hospitals in the treatment of their regular patients as well as the victims of civilian disasters. The excellence of the technic employed by these hospitals in preparing and administering plasma is evidenced by the fact that they have experienced less than 1 per cent of reactions with its use. These have been of the pyrogenic or urticarial types, which are rarely severe. The number of reactions reported is very close to the irreducible minimum which may be expected to accompany the intravenous administration of fluids.

The plasma reserve and the organization for distributing it have proved their value many times. One of the first incidents in which these reserves were used was the Cocoanut Grove Nightclub fire in Boston. In all, 1,308 units of plasma were used to treat 181 burned patients, most of whom lived. Their survival was due, in large part, to the prompt administration of adequate amounts of plasma. Of the plasma used, 833 units came from the Civilian Defense reserves in Boston, which amounted to 2,800 units at that time. The remainder was supplied by the U. S. Navy and the Red Cross.

In Rochester, N. Y., 57 units of plasma were used to treat 15 workers injured in an explosion at the Rochester Fireworks Company. Five workers burned in an explosion at the Tidewater Oil Company plant at Bayonne, N. J., required 24 units. Some of the other incidents in which these plasma reserves have been used are: the crash of a bomber into a Seattle, Wash., packing plant, an explosion in a munitions plant at Elkton, Md.; a war plant fire at Amsterdam, N. Y.; the explosion at the Congoleum-Nairn plant in Kearney, N. J.; the wreck on the Pennsylvania Railroad at Philadelphia; the Lackawanna Railroad accident at Wayland, N. Y., and the hotel fire in Houston, Tex.

On several occasions plasma has been supplied to Army, Navy, and Coast Guard stations in this country to meet an emergency when their own plasma was not immediately available in sufficient quantity. Such a case occurred last May at Abilene, Tex., when a column of soldiers marching at night was run through by a motorist. Plasma was requested at about 1 a. m. from one of our grantee hospitals at Fort Worth and was delivered to the station hospital, 150 miles away, by the Civil Air Patrol within one hour after the request was received.

The establishment and operation of blood and plasma banks in the larger hospitals has proved to be of great value in improving the treatment of the sick and injured. Although the most spectacular results are seen in the treatment of traumatic and burn shock, the ready availability of blood and plasma is resulting in better preoperative preparation of surgical patients who show decreased plasma proteins or anemia. Likewise, the adequate and prompt replacement of the blood loss which accompanies major surgery, prevents shock and keeps the patient in excellent condition during the opera-

tion. This permits the longer surgical procedures to be carried out without the need which so often exists to "finish the operation before the patient goes bad." Further transfusions of blood or plasma are often indicated during convalescence because of continued anemia or depletion of blood proteins. Convalescence is smoother and shorter when the blood components can be kept within normal limits. The blood bank also facilitates the treatment of the anemias, blood dyscrasias, and acute infections.

It is my belief that hospitals, equipped to prepare plasma and store plasma in the frozen state, will find increasing use for it in the treatment of infectious diseases. I should like to review the present status of this field and point out some of its possibilities.

The development of the present use of convalescent sera is due largely to the work done by the Serum Centers which have been established in a few large cities, such as New York, Chicago, Philadelphia, and Los Angeles. As a result, the medical profession at large has had little opportunity for personal experience with the various convalescent sera and is aware of their value only through the literature. However, the experience of these Serum Centers during the past several years has demonstrated that convalescent human serum is of therapeutic value. In their hands, it has been most satisfactory in the prevention and treatment of measles, scarlet fever, and mumps. For these diseases, the material is prepared by pooling the serum obtained from 25 to 50 donors bled within 4 to 6 months after recovery from the disease. After testing for sterility, such sera are placed in final containers of suitable size and either dried or stored in the frozen state until needed for use. Pooled normal adult plasma (or serum) is one-fourth as potent as these convalescent sera and equally good re-

sults have been obtained with both when given in proper dosage. Unlike the antisera prepared from immunized animals, the use of human serum or plasma is not attended by the danger of anaphylactic reactions, serum sickness, or the development of a sensitivity which would contraindicate the further use of such sera. The transmission of jaundice by transfusions of human plasma and serum requires further study. Fortunately, this is a rather rare occurrence.

In the prevention of measles (rubeola) and in treatment of the disease during the preëruptive stage, both convalescent serum and pooled normal adult serum (or plasma) have been equally effective in proper dosage. Since 95 per cent of the deaths due to measles occur in children up to 4 years of age, it is very important to prevent the disease, if possible, in this age group. The intramuscular administration of 10 to 20 ml. of convalescent serum, depending on the age of the exposed child, within the first 7 days after exposure, will result in 50 to 70 per cent complete protection and 20 to 40 per cent of modified measles. Since modified measles confers the same degree of immunity as is acquired from an unmodified case, it is desirable to attempt to modify rather than prevent the disease in children over 5. This can be done with fair regularity by giving one-half the dose required for complete protection. There is some evidence that the intravenous administration of large doses of serum also may be of some value in lessening the acute symptoms when treatment is begun after the eruption has appeared.¹⁻⁵

Scarlet fever convalescent serum has also been strikingly effective, and pooled normal adult material appears to give equal results if administered in proper dosage. Convalescent serum, given intramuscularly, in dosage of 10 to 40 ml., depending on the age of the

patient, and within 24 to 48 hours after exposure, will reduce the incidence of the disease among the exposed individuals from 10-15 per cent to only 1 per cent who show a typical course and 0.5 to 2 per cent who have mild or modified scarlet fever. Since this passive immunity lasts only 10 to 14 days, a protective dose of serum should be repeated every 10 days if exposure continues. In the treatment of scarlet fever, excellent results are also obtainable if the serum is given intravenously. The recommended dosage, if treatment is begun during the first 36 hours of the disease, varies from 20 to 100 ml. depending on age. In 75 to 85 per cent of the cases so treated, the acute symptoms subside in 12 to 24 hours.^{1, 4} The incidence of complications is reduced by 50 per cent and those that do develop are usually mild in nature. If the acute disease does not clear, repeated doses are indicated at 48 hour intervals. Almost as good results may be obtained up to the 6th day of the disease in uncomplicated cases. Even cases with complications are usually much benefited if they receive at least 3 standard doses at 8 hour intervals. It is worth noting that scarlet fever convalescent serum has given good results in several other diseases caused by the hemolytic streptococcus; such as erysipelas, pharyngitis, cervical adenitis, post-operative complications of mastoiditis, and pneumonia. Experience with the use of convalescent serum in conjunction with the sulfonamides has shown, at times, striking results due apparently to a synergistic effect of the combined therapy. Therefore, serum offers an alternative treatment when sulfonamides are contraindicated and an additional therapeutic agent in difficult cases.^{1, 3-8}

The development of mumps has been prevented in 90 to 95 per cent of exposed individuals by the intramuscular

administration of 20 to 40 ml. of convalescent serum, given within 1 week after exposure. Dosage again depends on the age of the individual. Prevention is, of course, most important in adolescents and adults to avoid the danger of orchitis which accompanies this disease. Thalhimer¹ and others have also used convalescent serum to treat the acute disease, and report prompt subsidence of acute orchitis when 40 ml. of serum is given intravenously.³⁻⁵

The Philadelphia Serum Center has had good results in the use of hyperimmune human serum in the prevention and treatment of whooping cough.⁴ This serum is prepared from donors known to have had whooping cough and who are receiving repeated injections of pertussis vaccine. The agglutinin titer of such serum is 1/1280 to 1/5120 as compared with a titer of 1/300 in the average convalescent. Ten to 20 ml. of this serum was given intramuscularly to 215 infants and young children during the first week after exposure. Complete protection was achieved in 78 per cent of the cases, 10 per cent had a very mild illness, 6 per cent had a moderate disease, and 6 per cent developed typical whooping cough, except that no complications were seen. This dosage of serum should be repeated every 5 to 7 days if exposure is continuous. Good results were also obtained in the treatment of the acute disease. One hundred and twenty-three of 315 cases treated were infants of 6 months or younger. The dosage employed was 20 ml., intramuscularly, repeated daily for 3 or 4 doses. Subsidence of the major symptoms occurred within 10 to 14 days in about 69 per cent of the cases, with a death rate of only 1.5 per cent. The Philadelphia group is now recommending that the intravenous route of administration be used in treatment of the acute disease and that larger doses

be administered. Currently, 60 to 100 ml. of serum is being given intravenously to critically ill infants and repeated if necessary.

The value of convalescent poliomyelitis serum has not been established. There are some who are convinced of its beneficial effect, but this point of view is not generally accepted. Levinson, who has had a large amount of experience with the use of convalescent poliomyelitis serum, is a firm believer in its value.⁹⁻¹¹ It is a difficult disease in which to gauge the effectiveness of any specific therapy, but he feels strongly that his observations indicate that the intravenous administration of adequate amounts of serum will prevent the development of permanent paralysis, if treatment is begun in the preparalytic stage, and that it will arrest the progress of paralysis, if treatment is begun later during the acute disease. Serum treated cases, according to his data, characteristically show a fall in temperature and pulse rate with clearing of the acute symptoms within 24 to 48 hours. It is his feeling that the poor results experienced by other investigators have been due to the employment of too small amounts of serum. His dosage schedule is 60 ml. plus 1 ml. per lb. of body weight, repeated every 12 to 24 hours, until results are obtained. One to three doses give good results in the majority of cases. Levinson states that in his experience pooled normal adult serum is also effective if given in twice the dose recommended for the convalescent material.

Recent experience^{11, 12} would indicate that both convalescent and pooled normal adult serum or plasma were of definite value in the treatment of cases of virus pneumonia seen during two recent outbreaks of this disease. A prompt fall in temperature with recovery from the acute symptoms was seen in the majority of about 70 cases so treated. Braley and Sanders recently

reported excellent results in a small group of patients with epidemic keratoconjunctivitis treated with convalescent serum.¹³

A few years ago, while conducting a study of the value of specific antisera in the treatment of the pneumococcus pneumonias, Taplin¹⁴ made a most interesting observation. Several cases were found in which a crisis did not occur, although an excess of antibodies was present as evidenced by the Francis test. The blood complement level was checked, among other things, in an attempt to determine the reason for the apparent failure of serum therapy. Six of these cases were found to have a deficient blood complement and were given 200 to 400 ml. of fresh plasma intravenously. All 6 cases had a typical crisis within 24 hours. Further investigation along these lines was conducted in 1941 by a group at the Syracuse College of Medicine.¹⁵ In addition to cases such as those described, a deficiency of complement was found to exist, at times, in other acute infectious and allergic diseases. For example, a deficient blood complement was observed during the first day of symptoms in one case of serum sickness and in one of acute nephritis complicating scarlet fever. Striking clinical improvement was noted in both cases following the prompt administration of 300 ml. of fresh plasma intravenously.

These interesting indications of the possible value of fresh plasma or serum in the treatment of acute infections and allergic syndromes are evidence that there may be various therapeutic properties of blood and blood derivatives as yet unexplored. More investigation must be carried out to determine the value of convalescent serum in poliomyelitis, virus pneumonia, and other acute infections. The evidence of the effectiveness of this therapeutic agent in the prevention and treatment of measles, scarlet fever, mumps, and

whooping cough is sufficiently important to warrant the interest of every state health officer.

It may be desirable for public health laboratories to undertake serum center projects. This may be accomplished by interesting and aiding large hospitals to expand their blood plasma banks to include such a service, or by establishing a plasma or serum service in a public health laboratory. It is also important that the reserves of pooled normal adult plasma, developed to meet the needs of those injured in disasters, be maintained after the war, so that injured civilians can receive the same excellent and prompt care that has been possible in most of the serious accidents occurring during the past year. This would seem to be the logical interest of health officers who should promote, properly control, and further such a program. The States of New York, Michigan, Illinois, Vermont, Iowa, and Texas are already engaged in or interested in establishing such a service.

The development and maintenance of plasma reserves for the treatment of large numbers of injured and an adequate convalescent serum service constitutes a real challenge to those charged with guarding the health of the nation.

Problems in Population Estimation^{*}

ELBRIDGE SIBLEY, PH.D. .

*Division of Statistical Standards, United States Bureau of the Budget,
Washington, D. C.*

IN addition to their normal responsibilities, public health officials now have the task of safeguarding the health of millions of Americans who have moved from place to place during the war emergency. Some idea of the magnitude of their problems can be gained from the estimate that perhaps as many as one-sixth or one-seventh of the inhabitants of the United States have moved from one county to another since the 1940 Census was taken. To meet this challenge intelligently health officials need to know how many and what kinds of people now live within their jurisdictions.

Actually no one knows exactly how many people have moved throughout the country, whence they have departed, and where they have arrived. Although people are supposedly more important than material goods, it is harder to obtain adequate statistical information concerning the composition, characteristics, and distribution of population than to make detailed inventories of the commodities which people produce or consume. It is especially difficult to obtain adequate current population data in the abnormal situations where they are most acutely needed. Census methods which have sufficed in normal times cannot be applied often or quickly enough, and the ingenuity of statisticians is called upon to develop new

methods of currently keeping track of our rapidly moving people.

Thus the American Public Health Association, along with organizations concerned with problems of labor supply, education, and various other community services, should be interested in promoting the development of adequate current population statistics.

Registration officials have a dual task: to provide official documentation of facts about individuals and to produce raw or finished statistical data. This paper is concerned with the second function. It may be well to begin by summarizing the principal uses of vital statistics, since this paper is premised on the assumption that there is no time today for statistics unless they are useful. Vital statistics are used:

1. To describe the past and current growth of the population and to predict its future trends.
2. To describe past and present health conditions as reflected in mortality and morbidity rates and in life tables; and to anticipate future trends in the light of these indices.
3. To appraise the effectiveness of specific public health measures.

To accomplish almost any of these purposes it is essential to know or to estimate the size and composition of the population as of definite dates, past, present, and future. As a basis for computation of crude vital rates, data on the total population are essential; for more refined analysis involving specific and adjusted rates and life tables the composition of the population by age, sex, race, and sometimes other characteristics must be known or assumed.

^{*} Presented at a Joint Session of the American Association of Registration Executives and the Vital Statistics Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

Population data are needed not only as the denominators of various vital rates and indexes but also for direct use in planning: (a) land use and the provision of public utilities and other community facilities, (b) the apportionment of financial aid and central governmental services, and (c) especially in times of war-begotten scarcities, the distribution of consumers' goods.

To make a further catalogue of things which are obvious but nevertheless have to be thought about, there are a half-dozen different ways of measuring or estimating the population of a given area:

1. Complete census enumeration
2. Continuous population registration
3. Mathematical interpolation and extrapolation of the net trend of population growth as indicated by successive censuses
4. Analytical and synthetic projection of population changes, as distinguished from the crudely empirical projection of the net trend
5. Estimation from *ad hoc* sample enumerations
6. Estimation from data collected for other than demographic purposes

To take a complete census is the most forthright and foolproof method of determining how many people there are in a given area at a given time. But it is also a very expensive procedure, and as you all know the federal government has so far seen fit to undertake it only once every 10 years. For some decades past the idea of shortening the interval between national censuses to five years has been widely advocated, but at present most people's attention has been directed to the task of finishing a rather large war. At best a considerable interval must elapse between complete censuses, whether it be 10 years or 5. For the purposes already mentioned it is necessary to know something about the population all the time and not just at isolated census dates.

The Scandinavian countries with their systems of continuous population

inventories have long been the envy of American statisticians. Last year the Vital Records Commission, appointed by Federal Security Administrator McNutt, seriously studied the feasibility of registration of the American population and the establishment of continuous registers which would be kept up to date by accounting for all births, deaths, and changes of residence, as well as perhaps all marriages and divorces. The commission sketched the main outlines of a concrete plan for such registration and recommended that it be undertaken at once "if deemed essential to the war effort." Consultations with the war agencies of the federal government led to the conclusion that it would be unwise to attempt to inaugurate such a system at present in view of the very large expenditures that would be necessary and in the face of the wartime shortage of man power. It was generally agreed that if universal registration were to be undertaken there ought to be definite assurance of sufficient funds and adequate personnel to do a thorough and accurate job. Experience elsewhere, notably with the Canadian National Registration of 1940, has amply demonstrated the futility of doing a half-way job. So for the present a nation-wide system of continuous population registers appears to be out of the question.

Interpolation or extrapolation from crude census data is the cheapest, easiest, and often the only available method of estimating the population for inter-censal or post-censal dates. For purposes of inter-censal estimation the choice of a mathematical function to describe population growth does not present very great difficulties. If the population is fairly stationary the errors which may be introduced by application of one function rather than another are small in comparison to the inaccuracies of the census data themselves; if the population is growing or

declining rapidly the chances are that the fluctuations of its growth from time to time will outweigh the errors arbitrarily introduced by any particular mathematical formula. For example, the population of the city of Los Angeles more than doubled between the censuses of 1920 and 1930. Yet the relative discrepancy between interpolated estimates based on arithmetic and geometric increase reached a maximum of only 8 per cent in the middle of the decade. On the other hand, in extrapolating trends beyond the last census date, the selection of a function may introduce serious and rapidly increasing discrepancies. Again taking Los Angeles as an example, projection to 1940 of the geometric rate of increase observed in the preceding decade yields an estimate 30 per cent greater than projected increase on an arithmetic basis and 80 per cent greater than the actually enumerated population. By 1950 the geometric estimate exceeds the arithmetic by nearly 60 per cent. Obviously it is unsafe to rely on either one, since some of the conditions which produced the rapid growth between 1920 and 1930 were undoubtedly transitory.

The logistic growth curve described by Pearl and Reed and validated by their experiments with fruit flies in milk bottles has an air of universal truth about it which might lead the unwary to apply it uncritically to the growth of any and all populations; but the authors themselves would disclaim any such indiscriminate use of their formula. They recognized that, although cities, counties, states, and nations are somewhat analogous to colonies of *drosophila*, there are some respects in which the comparison is invalid. Even in such large and relatively stable aggregates as whole nations, population growth refuses to conform always to any single formula. The more terms one introduces into the formula the closer the fit that can be obtained to observed

data, but the weaker the *a priori* grounds for projecting the curve into the future. Smaller population aggregates such as cities and counties fluctuate even more wildly in response to the disorderly motives and whims of human beings.

Somewhat more dependable but still arbitrary estimates of post-census population growth can be derived by what we may call analytical and synthetic methods of projection. If adequate records are kept of births, deaths, and inward and outward migration, it is obviously possible by simple addition and subtraction to determine how much the population has changed since the last census. This procedure is applicable to the United States as a whole but not to any of its subdivisions, because comprehensive internal migration data do not exist. The well known estimates of Thompson and Whelpton are derived by applying age-specific birth and death rates successively to the known population at a census date and to the computed population at subsequent dates. Allowances can be made for anticipated increases and decreases in the specific rates and for assumed volumes of net migration.

Again, this method of estimation can be applied with greater confidence to the entire nation than to individual states or cities because in the case of the latter not only net migration but also nonresident births and deaths are imponderable elements. As Thompson and Whelpton have taken pains to observe, their estimates, like those based on some general empirical growth curve, are strictly speaking not predictions of the actual population at future dates but rather computations of what that population would be if certain explicitly assumed conditions should prevail. In this sense they are very useful instruments for anticipating the possible results of given conditions. They do not provide a satisfactory base for com-

puting vital rates, nor can they indicate to a public housing administrator, for example, how many houses are needed or will be needed at a given time.

Sampling enumerations of population have the advantage of being much cheaper than complete canvasses and can serve some purposes just as well, but there are definite limitations to their use. Some time ago the Bureau of the Census formulated detailed plans for nation-wide annual sample censuses of population, to supplement the complete decennial censuses. The project, like many others, has become at least temporarily a casualty of the war. Assuming that a sample of between 1 and 5 per cent of the population were to be canvassed, it would be possible to obtain very reliable figures for the country as a whole and for very large cities or other areas with a large aggregate population, but those changes in the population of small areas which are often of crucial practical importance would not be measured. A couple of years ago plans were also drawn for a special census of the Washington, D. C., metropolitan area, using a considerably larger sample. This project also failed to materialize.

The Monthly Labor Force Survey, initiated in 1939 by the Work Projects Administration and now carried on by the Special Surveys Division of the Bureau of the Census, is a notable example of the use of so-called stratified sampling to obtain estimates for a large population—in this case the entire labor force of the nation—by canvassing a relatively very small sample. Based on returns from small numbers of households in 64 counties, the results of this survey may be regarded as indicative of nation-wide conditions, but it is impossible to derive estimates for smaller areas.* Sample censuses of Chicago and the State of Michigan were

made in the mid-1930's under the auspices of emergency relief agencies. One of the hazards involved in applying random sampling to census-taking was illustrated in the latter project when a supervisor discovered that one of his canvassers who suffered from an inferiority complex avoided ringing the doorbell of any brick house and always visited the next wooden house instead. Another large-scale application of sampling to population estimation was the series of studies of in-migration to some 70 centers of defense industry made by the Work Projects Administration in 1941 and 1942. The coverage of these surveys usually included a random sample of dwellings throughout the city and a more intensive canvass of low priced hotels, tourist camps, and the like.

In general, it is easier to derive from sample canvasses frequency distributions of population characteristics than it is to determine the absolute size of the population. By the application of probability theory it is relatively easy to determine in advance how large a sample will be needed to yield sampling variances within predetermined limits, but no amount of mathematical theory can assure the selection of a sample which is truly representative of an unknown stratum of the universe.

Stratified sampling (or, to use an etymologically less inept term, purposive sampling) is for many purposes more efficient than purely random sampling but it can be properly used only if the dimensions of the various strata or segments of the universe are fairly well known in advance. Thus, for instance, this method is not very well adapted to estimating the population of a community which has been undergoing rapid change.

To meet the inescapable need for some kind of local population estimates in the absence of a recent general census and if a special sample census is not

* A new sample design was adopted late in 1943.

feasible, recourse is often had to various series of data which are collected for other purposes. Among the more commonly used sources are the following:

School enrollments and censuses of school children—The number of children unfortunately bears no constant ratio to the total population and this ratio is most likely to be abnormal in precisely those rapidly changing communities for which current population estimates are most urgently needed.

City directories—These customarily list adults only. City directory listings are sometimes used in conjunction with school census data, each supplementing the other.

Voting lists, tax assessors' lists, and lists of public utility customers—All of these are selective and especially likely to omit persons who have recently moved into a community. They are also subject to more or less expansion and contraction with changing economic or political circumstances.

Registrations for ration books—Registrations of consumers for food rationing provide at present the most nearly satisfactory nationwide source of current population data. Certain categories of persons have been excluded from receiving food ration books. These include members of the armed forces (except those who do not eat at organized messes) and inmates of institutions. It is possible, in most cases, to obtain fair estimates of the latter from other sources. The Bureau of the Census has published estimates of the civilian population of each county on the basis of registrations for War Ration Book 1 as of May, 1942, and is preparing similar estimates from the records of distribution of War Ration Book 2 as of March, 1943. War Ration Book 3 was distributed last summer through post offices, and applications for this book have been filed in such a manner as to make it impractical to derive population estimates for counties or other political subdivisions. Applications for War Ration Book 4 which were received in October, 1943, will provide the basis for a new set of county population estimates. Heretofore only the total population has been estimated from ration book registrations. In connection with the distribution of Book 4, however, plans have been made for sample tabulations of age by sex for selected areas which are known to be congested or to have experienced unusual population growth. These tabulations are to be made by the Bureau of the Census directly from the original application blanks which will be shipped to Washington from the selected counties. Although no plans have

been made to do so, it would be possible also to extract data on the sizes and the age and sex composition of family groups.

CONCLUSION

This survey of methods of estimating population should indicate that it is difficult, especially in wartime, for the central government to provide data which will meet all local needs. Local needs are varied and frequently urgent. The Vital Records Commission, after discussing the potential usefulness of a national registration scheme to the federal government, observed that it would be of even greater value at a local level than for the nation as a whole.

Undoubtedly, a system of continuous population registration would provide a local community with more adequate current information about its population than could be obtained by any other means. While it has been determined to be unfeasible to undertake nationwide registration under present conditions, perhaps the registration officials of some unusually self-conscious and civic-minded communities might try to enlist the support of other local officials for some experiments along this line. If the obstacles to establishing a local register are overwhelming, it might be possible at least to develop other procedures for obtaining periodically better indications than now exist of local population changes. Such experiments might serve as models to be gradually copied throughout the country or as horrible examples to be avoided. At present we have not enough of either.

Few successful managers would dream of running a business without maintaining continuous inventories of their stocks in trade; the time is past when the affairs of a community could be well conducted without knowing of how many and of what kinds of people it is composed. Here is a challenging opportunity and need for registration

officials of cities and states to look beyond their traditional function of keeping birth and death records, and to pioneer in developing better systems of population accounting.

In this pioneering they should enlist

the support of numerous local official agencies and community organizations. Various federal government agencies would, I am sure, be glad to assist with technical consultation, but local initiative is greatly to be desired.

DISCUSSION

GRACE C. SCHOLZ

*Statistician, Executive Office for Rationing, Office of Price Administration,
Washington, D. C.*

MR. SIBLEY'S summary of methods of population measurement and estimation leaves little to be added. I believe that the most pertinent comments that I can make deal with the most recent available sources of data which serve as bases for population estimation, that is, the national registrations of consumers for War Ration Books.

As has been done in Books One and Two registrations, figures, by county, obtained from Book Four will be compiled by the Office of Price Administration. Issuance subsequent to initial registration and the surrender of books, as reported monthly, will be used to adjust the initial registration data and subsequent releases issued. In addition, to supply the demand for data at the local level, the Bureau of the Census will tabulate age and sex distributions for the civilian population of all cities of 50,000 and over, and for a number of rural counties which have been selected as critical areas by government agencies whose operations will be aided by having such information available. Approximately 500 counties are included in those selected, and sample tabulations will be made for about 300 areas, some areas comprising several counties. This will be done on the basis of application forms for Book Four which, for the counties selected, will be

forwarded to the Bureau of the Census. It is also contemplated that certain family data be tabulated in selected areas if technical methods can be found to determine family composition from data listed on the application forms.*

As Mr. Sibley has pointed out in discussions with representatives of the OPA, although I do not think he has mentioned it in his paper, national estimates of age distribution and sex distribution are better obtained from other available sources than this ration book registration, even though estimated from less current data. On the other hand, data for critical local areas cannot be accurately estimated from less current information, because of the very factors that make the areas critical, e.g., recent large scale population shifts.

The OPA has sought, since the time of the Sugar Registration, that is, the War Ration Book One registration, to confine its requests for information from the registrant to those items incidental to the registration and necessary to the administration of its various rationing programs. Registration data within the OPA have served a number of administrative purposes. County figures have been used as the basis for dis-

* Some doubt has arisen as to whether all of these tabulations will be completed. Present indications are that only figures on age-sex distributions for a number of selected areas will be made available.

tribution of ration forms, probably the largest distribution of printed material that has ever been undertaken. Allotments of sugar, processed foods, and meat are made to industrial users on a basis which utilizes county registration data in its computation. In budgeting for field and local board OPA personnel, county registration data supply one guide by which size of staff is regulated.

When the OPA requires statistical information, as, for example, age-sex distributions in local areas in any of its rationing programs, this requirement is always duplicated by another government agency—the agency that will direct the OPA to ration that commodity. For example, if the OPA should be directed to ration milk, it will require age-sex distributions of the population in the areas to be rationed. This same information is now required by the War Food Administration.

Registration data have not always been issued to the public, but they have always been made available to those government agencies requesting them. When registration counts have been issued by OPA they have always been accompanied by the admonition that these registration data were not population figures and should be properly interpreted or qualified in their use. Particularly, they have been supplied to the Bureau of the Census in order that that agency, through its established facilities, might properly use them to serve as the basis for civilian population estimates.

There are a number of reasons why registration data cannot be assumed to represent civilian population data. These reasons can be divided into two groups—those that affect the initial registration figures and those that influence current data, that is, data corrected for issuance subsequent to initial registration and surrender of books. In the first group the following may be mentioned:

1. War Book Registrations have been associated in the public mind with specific commodities, e.g., Book One was associated with sugar and there was little incentive for people having no use for sugar to register, until Book One became a requisite for Book Two. Book Two was associated with processed foods and we may assume that until Book Two was also used for meat there were some persons who did not make application for it. Book Three was associated with the continuing need of stamps for meat and for the next shoe stamp. There is an increased incentive to acquire Book Three since it has been announced that it is a requisite for Book Four. Now that the plan for use of tokens has been generally discussed, and it is probable that Books Three and Four will be made to last for several years, there is strong inducement to acquire both, even though no one commodity has become associated in the public mind with Book Four.

2. Differences in definition of institutions by the Bureau of the Census and the Office of Price Administration make difficult the determination of the size of the group of institutionalized persons who do not apply for War Ration Books.

3. Members of the armed forces not eating in organized mess were excluded from the initial registration for Book Three, although that group was included in the initial registration for Book Two. The size of this group has been roughly estimated at 400,000.

4. Registrations have been conducted at a time characterized by population movements making for faulty initial registration and increased late registration, and that late registration not always at the place of residence.

5. So much of the completeness of registration at the local level depends on the competence of the rationing and registration machinery and on the effectiveness of the publicity given the

registration, that there is bound to be considerable variation from county to county. The dependence on field operations in the registrations has varied. Book One issuance was entirely centrally controlled; in Book Two more opportunity for local planning was permitted. Book Three was almost entirely distributed according to a national office plan, while Book Four again becomes a schoolhouse registration but with considerable latitude for field planning in its distribution (each of the administrative regions of OPA established its own plan for distribution in accordance with certain broad outlines established by the Washington office).

The maintenance of currently correct registration data is dependent upon an accurate knowledge of late issuance of War Ration Books, of births, and of surrender of ration books due to entrance into the armed forces, death, or admission to an institution (e.g., mental hospital or prison). The attempt to collect surrendered books has not been too successful so far in spite of the

efforts of a number of organized groups. However, every attempt is being made to improve the machinery by which books are surrendered. Because of the incompleteness of current registration data, in the case of War Ration Book Two, the public release of late issuance data, on the advice of Census experts, has been stopped as of April 1.

While registration figures for War Ration Books may serve to supply certain estimates of civilian population in the country as a whole, or in smaller areas, they could not supply even a portion of the detail that a national registration system such as that proposed by the Vital Records Commission would furnish. While it would be unwise not to make all possible use of whatever registration data may incidentally be provided by administrative needs, such a registration must serve primarily the purpose for which it was initiated. A War Ration Book registration does not provide a particularly good vehicle for collecting statistical data, but until a better one of equally recent date is provided, it must serve as best it can.

OLD NOSTRUM RIDES AGAIN

FOR some reason or reasons, perhaps connected with public psychology in war or in some way related to the burden of taxes, radio has rejuvenated patent medicines. In a great many of the better spots of the better broadcasts one is assailed by authority-timbred tones which bid the public strengthen itself with some special brand of vitamins or which emphasize the value of a particular panacea that, because it is like a shotgun prescription, will remove hair or curl the whiskers, as the sex might be. Or again the same long-suffering public is exhorted to purify its blood, to waken its liver, to unclog its nostrils, to move its bowels. Often too, these succulent radio voices add a touch of mystery and dignity by the mouthing of chemical terms. They set forth anatomical relationships clearly enough to be understood by a child but not by an anatomist; and too frequently an amazingly simple physiology is inferred. Torch singers and sopranos take up the refrain and drag into millions of living rooms little songs and jingles, some of them very catchy too, all to the glory of self-dosage; and often it is only through the courtesy of some proprietary that one gets spot news or good music or a thrilling drama of the air. Some of these radio prescriptions are new and sail confusingly in the wake of modern science. Others are so hoary in their iniquity that the medical profession was under the impression they had been laid to rest by federal laws as to claims and labels, and newspaper ethics as to advertisements. But they live again on the radio: cut a little smoother and thinner, but the same old sausage.

Regardless of the particular proprietary that sponsors and irrespective of the broadcasting company, or of script writers, performers and announcers, there is a strong tendency in most programs to lead listeners so easily and pleasantly down the path of self-diagnosis that self-treatment seems quite logical; and the uninitiated can hardly wait to get to the drugstore. From an advertising standpoint, no doubt, such an outcome spells shining success: there is something to be sold, and by the eternal, it is being sold; and the contracts go rolling along. But from the standpoint of the medical profession and of those interested in the public health this radio-nostrum alliance is a discouraging and alarming phenomenon. How or when the situation may be rectified, no one knows, for both interests are powerful. The radio industry is literally bursting at the seams with vigor and ambition, possessing in full measure both the promise and crudeness of youth. It is

apparently willing and able financially to fight for what it believes to be its prerogatives, and judged on the basis of past programs, these prerogatives include the right to further in the United States a patent medicine guzzling citizenry. The patent medicine industry for its part is no babe in the woods when it comes to taking care of itself. It knows just where effective pressure may be put and just how to put it; it knows just where the legal ice is thin, and, correspondingly, it knows where it may safely do a therapeutic razzle-dazzle.

For the above reasons and others, one may not hope for any early restrictions in radio advertising of patent medicines. It is too profitable an alliance for any of the high contracting parties to permit the public to "infringe" and, further, it is tied up with that reform-defying, resistance-smashing and magic institution, Commerce. And ladies and gentlemen, when majestic Commerce enters into any situation the lowly and poor relations of government and society had better seek shelter, for public health history is replete with records of the pressures that commercial interests can bring, such as denial of the presence of an epidemic or insistence upon the right to sell inferior goods, including drugs, to the unsuspecting at home and abroad. Legislators, health officers, physicians, and others interested in the public welfare have thus learned that in any clash between public health and Commerce, the public is willing to take a long and thorough drubbing before it rises in its wrath. Fortunately, but usually at long last, the Right may hope to prevail. In the meantime, and in the present radio patent medicine situation, one is inclined to ask, "How long, O Lord, how long?"

And not the least distressing part of the situation is that these patent medicine shows, in their radio excellence, put to shame the sincere but nevertheless dull efforts of conventional health education.

TWENTY-FIVE YEARS OF FRUITFUL PHILANTHROPY

THE Commonwealth Fund, which was founded just before the Armistice in 1918, reviews its experience from war to war in the *Annual Report* for 1943. It is not only because the Fund has spent \$41,000,000 "for the welfare of mankind" during this quarter century that it has significance for the public health professions. In quantity that is no mean sum. In emphasis it represents a special concern with public health, for \$28,000,000 has been expended for the physical and mental well-being of the race.

It was a former President of the Rockefeller Foundation, Dr. George E. Vincent, who, when asked to justify the investment of a major portion of income in public health activities, declared that this field held a supreme advantage because one could measure the results with reasonable precision. The Commonwealth Fund has not neglected the critical testing of its health enterprises. Through the auspices of the Fund the late Dr. W. Frank Walker made his distinguished contributions in the realm of appraisal.

Giving away money has its own problems and pitfalls. Long ago Horace said, "Money is a handmaiden, if thou knowst how to use it." A giver need not deal in millions in order to appreciate the candor and the objectivity with which this report appraises the Fund's changing program and its effort to achieve "that middle course between the inflexibility of fixed endowments and the inconsequentiality of random giving." The flexibility of this program is well shown by the frank evaluation of the Fund's early large scale adventure which took the form of a series of demonstrations of child health services as part of the local

public health program. These demonstrations "set a pattern for a few good local health departments," but "on the whole they were disappointing as instruments for the improvement of public health service."

The Director declares that, in spite of the imperious demands which war makes on givers, the special function of foundations is to put money at work at slow, constructive, undramatic tasks that look to the future rather than to the immediate present. Few better statements are on record of the place for this kind of institution, the American foundation.

Besides the war service and foreign relief expenditures, which were sizeable at the beginning and at the end of the twenty-five year period, four major groups of activities are notable in the record. They are health services, medical research, mental health, and international fellowships. In these groups the contributions of the Fund show trends generally upward in the first two activities by five year periods. Contributions to mental health are declining; the British Fellowship program has been suspended for the duration of the war; the Fund is now offering a limited number of fellowships in medicine and public health to Latin American countries. Commendable is the determination to publish in some detail the purposes for which all grants were made. This is an obligation which a private trust certainly owes to the society which allows it to exist and is a policy which might well be emulated by all similar foundations.

"The Fund has been interested for many years in tools by which local health work can be appraised and guided. Through the Committee on Administrative Practice of the American Public Health Association and through its own Division of Health Studies it aided in the development and application of the *Appraisal Form for Local Health Work*, used first as a formal yardstick of public health performance and later as a mirror by which the health department could see its own progress or retrogression from year to year. Whatever the metaphor, such a device needs frequent adjustment, and it has now been refashioned in a form which promises even greater usefulness. During the past year 134 local health departments have reported to the American Public Health Association their statistical performance with respect to a carefully selected group of indices, e.g., percentage of children under five immunized against diphtheria, percentage of infants under nursing care seen within one month of birth, percentage of contacts on the tuberculosis register examined by x-ray, and so on. These reports are then charted so as to show, for any particular index of accomplishment, the upper and lower quartile and the median, so that any given health department can compare its own record with that of the group as a whole, confident that the standard so fixed is in no sense arbitrary but an actual reflection of current practice. Large and small health departments are differentiated on the chart so that due allowance can be made for variations in working resources. All the statistical work on this material has been done in the Division of Health Studies and the first year's output, prepared in simple and inexpensive form, has been widely distributed and warmly received."

Other coöperative ventures between the Fund and the Association include the series of state health studies conducted during the last six years by the Committee on Administrative Practice, with assistance from the Fund, and the work of the Subcommittee on Local Health Units which, for the first time, is obtaining the facts wherewith the overall picture of health unit structure in the United States may be drawn. These are the slow, constructive, undramatic tasks to which the future belongs. There is food for thought and reason for hope in this report.

A SUGGESTION FOR GOOD SCHOOL HEALTH PROGRAMS

This statement by Dr. John Oppie McCall, Director, Murry and Leonie Guggenheim Dental Clinic, New York City, is based on notes made at the Workshop of the School Health Section on October 12, 1943, at the time of the Association's Wartime Conference and 72nd Annual Business Meeting.

The object of education is the total development of the child. In this his health is just as important as his grasp of arithmetic, geography, etc., and must receive equal attention from the school organization.

Health care of the school child requires health education and health testing and, in addition, emergency care. Since all of these activities will be carried on in the school, the Board of Education must see to it that they are carried on in a proper manner—must, in a word, have over-all charge of administration. Since this is a branch of public health service, the planning and execution of the health services mentioned must be developed in coördination with and have the approval of the local public health authority and reflect the best judgment of the medical, dental, and nursing professions. To achieve this coördination of professional authority a school health advisory committee may be organized by the school administrator.

Health services in the school must meet three criteria: soundness, economy, and availability when needed. Utilization of the classroom teacher as an integral member of the health team is needed to satisfy these criteria.

This implies that the teacher, both in her professional training course and in subsequent in-service training, shall be indoctrinated with the concept of the importance of child health, placing it on an equal footing with the usual classroom exercises.

At a time when the present primary and secondary school programs are under fire and are considered to be in need of modification, the introduction of this broader concept of education is timely.

It is the classroom teacher who sees the child every day and throughout the school day. She is the first to see signs of incipient ill health, such as rashes, undue listlessness, etc., to detect evidence of faulty vision or hearing, or other defects. She may properly apply certain screening tests so as to conserve the time of nurses and physicians. This means that she should be trained in the science and art of health care procedures to an extent that may be agreed upon by joint action of medical and educational authorities.

Screening tests which the teacher can make with a modest amount of training include: vision testing, audiometer testing, dental inspection. To do these things properly requires that she should be given, during her course, a certain amount of fundamental biologic instruction such as is used as an introduction to the nursing course, e.g., anatomy and physiology, both general and of the eyes, ears and teeth, chemistry of the body tissues and foods, nutrition, bacteriology, and hygiene.

Health education enters into the picture as well. Health education is a sterile thing unless applied in practical everyday life. The school has an opportunity and an obligation to vitalize it. Daily health inspection by the teacher,

implementing the course of instruction in this subject and supplemented by special testing at appropriate intervals, provides the basis for such vitalization.

With the type of training indicated here the teacher will watch the health of her pupils, will know when to refer them to the school nurse for further evaluation. The nurse in her turn will decide when the child needs medical attention. Neither the nurse nor the physician need have his time taken up unnecessarily. The teacher will keep and file with her other records the primary health record of the child, making notations when reference has been made to nurse or physician.

The need for universal medical examination will vary, being influenced by general health levels in the community, occurrence of epidemics, etc., as well as availability of personnel. The time and energy of professional personnel should therefore be allocated on the basis of need rather than to have an invariable stereotyped pattern (annual examination) followed. However, annual dental examination by dentist or dental hygienist is needed because of considerable annual increment of dental caries.

FACTS ABOUT NURSING, 1943

One wishes that as many facts about the public health profession could be brought together in as convenient a compendium as the Nursing Information Bureau of the American Nurses Association has done in the booklet *Facts About Nursing, 1943*. Almost anything you want to know about nursing can be found therein. The number of nurses in the country, the number serving with the armed forces and in federal nursing services, the number of student nurses enrolled in nursing schools, the number graduated, student withdrawals, tuition fees—all these data are assembled. There are sections on private duty, hospital, and institutional,

and public health nursing; the American Red Cross Nursing Service and military nursing. Useful tables occur unexpectedly, like the one on enrollment in Blue Cross plans at the end of the hospital section, and like the cost of living table satirically and thought-provokingly included after the figures on working hours and salary ranges. The National League of Nursing Education and the National Organization for Public Health Nursing coöperated in the compilation. Copies of *Facts About Nursing, 1943* may be obtained from the Nursing Information Bureau, American Nurses Association, 1790 Broadway, New York 19, N. Y., at 25 cents each.

PUBLIC HEALTH IN NEBRASKA

The Nebraska Health Planning Committee, an unofficial organization made up of representatives of farm groups, urban organizations, University of Nebraska, and official representatives of the State Medical and Dental Associations, and the State Department of Health, has done an interesting interpretive job on Nebraska's recent health legislation. Under the title "LB 295 Gives the Green Light to Local Health Departments," it outlines in lay language and by way of 26 questions how localities may go forward in providing necessary public health service under the terms of the act which permits single or multi-county health units. One of these questions is "How Would a Local Health Department Serve My Family?"

The question "How Would District Public Health Units Be Determined?" is answered as follows: "In drawing up their own health districts local citizens may . . . find valuable help in the recommendations of the American Public Health Association." The committee then outlines briefly the June, 1942, resolution of the American Medical Association on local health service,

the setting up of the Subcommittee on Local Health Units of the A.P.H.A., and summarizes the recommendations of this committee as to size, area, combination of urban and rural areas of counties, and ratio of physicians and general hospital beds to population.

Answering the question whether every county may have a health department, the Planning Committee says "A county with a population of less than 60,000 should not attempt to set up a county health department unless the assessed valuation of property is sufficient to raise the necessary funds for the county share of the support of the local health department. For purposes of administrative efficiency and economy the majority of counties will find it most satisfactory to pool their financial resources with one or more adjoining counties to set up district health units."

This recommendation would appear to be approval in a very real and practical way of the 50,000 population set by the Subcommittee on Local Health Units as a minimum able to justify and afford adequate full-time health service, since only two of Nebraska's 93 counties have populations of over 60,000.

HEALTH PRACTICE INDICES

The Committee on Administrative Practice of the A.P.H.A. reports that its new publication *Health Practice Indices* is being very well received. Following the initial distribution to state and local health departments, about 800 copies have been sent out in answer to requests from health departments, health associations, other agencies and individuals scattered over 40 states and Canadian provinces.

Excerpts from the various comments received from state, city and county health officers are presented for interest.

"This booklet contains a world of helpful information."

"It is an excellent booklet and provides

a method whereby we may evaluate our services in the community."

"I am very much pleased with the copy of *Health Practice Indices* which you sent me. I should like to have copies of it for our 23 county health officers as well as our bureau chiefs."

"We believe that a study of these findings by a carefully selected group of individuals in our own community would be very helpful."

"We would like very much to become part of a reporting area for health practice indices."

"It is an excellent handbook for health officers. It quickly points out the weak spots in one's own program."

"I found the material very instructive and interesting. Would it be possible for us to obtain about 200 copies?"

"It is my purpose to use my figures and then try to approximate the line in order that I may compare my city with others. I plan on lantern slides so that I may use them in talks."

"The development of a national reporting system would be a significant improvement to public health practices. Locally the 'Indices' will be a real aid to the health officer in stimulating higher health standards. In a community with a new health department like ours, people are very pleased to hear that there have been no cases of small-pox in the last five years, but the fact that only 20 per cent of children below five years are vaccinated makes no impression on them. Or when we tell them that only 65 per cent of our people drink pasteurized milk they smile and say: 'Why that is wonderful, five years ago nobody drank pasteurized milk.' By showing them where other communities stand I think that the shocking index of the community can be raised."

The committee plans to study the use of the Indices in the field and assist in securing increasing accuracy in recording. Following the receipt of the 1943 *Evaluation Schedules* in March material will be assembled for the second issue of *Health Practice Indices*. The new booklet containing the 1943 experience will present material in the form used with most of the previous charts together with charts of information not previously included. An effort will be made to release this publication some time in August.

TIME SAVING TIP FROM A COMMON-WEALTH FUND NEWS LETTER

"Dr. Frank L. Roberts, professor of preventive medicine at the University of Tennessee, who visited Mexico and Guatemala last summer on an advanced fellowship from the Fund, tells in his report of a village in Vera Cruz which recorded an astonishing number of deaths from lepra (leprosy). The state health officer investigating the matter found that the local registrar had formed the convenient habit of ascribing all doubtful deaths to lepra because that was the shortest word in the official list of causes of deaths."

DISEASE OUTBREAKS IN THE UNITED STATES CONVEYED THROUGH VARIOUS CHANNELS

The States Relations Division, Sanitation Section, of the U. S. Public Health Service, Washington, has recently published four reports which describe respectively disease outbreaks conveyed through water, through milk and milk products, through foods other than milk and milk products, and through undetermined vehicles in the United States in 1942. These are according to reports by state and territorial health authorities and by certain city departments of health. These tabular statements gather together in one reference a considerable number of outbreaks. The report on water (A-1) records 6 outbreaks of dysentery, 37 outbreaks of gastroenteritis, and 9 outbreaks of typhoid fever. In the milk report (B-1) there is apparent a lack of uniformity in diagnoses as between food poisoning and gastroenteritis; 2 outbreaks of scarlet fever, 4 of septic sore throat, 5 of typhoid fever, 5 of undulant fever, and 1 of diphtheria (possibly conveyed through milk) are reported. The report on foods other than milk and milk products (D-1) includes 7 outbreaks of botulism, many food-poisoning and gastroenteritis out-

breaks, 9 outbreaks of trichinosis, and 4 of typhoid fever. Epidemiologists seeking to understand the relative importance of outbreaks associated with these various channels will be interested to study these reports.

THE NATIONAL ASSOCIATION OF MANUFACTURERS SPEAKS UP ON INDUSTRIAL HEALTH

No less an authority on what is good for business than the National Association of Manufacturers marshalls facts and figures to show that an industrial health program "pays" in terms of dollars and cents for the small as well as the large plant in peacetime and in war. The arguments are presented as part of a comprehensive study entitled "Health on the Production Front" by Victor G. Heiser, M.D., Medical Consultant for N.A.M. "The annual net profit to the average plant of 500 employees," Dr. Heiser says, "from the operation of a health program is \$5,611," while "the yearly loss to a company of 500 employees which operates without a health program may be seen to be \$39,900."

The information in "Health on the Production Front" of which the chapter "Do Good Working Conditions Pay?" is only a part, is keyed to the small plant, since as Dr. Heiser says, the problem of providing a health program for the small plant (fewer than 500 employees) has been "baffling," though the small plants of the country employ about 60 per cent of all industrial workers, now estimated to number 20,000,000.

There are four major divisions in the booklet: "Health of the Individual Worker," "Hygiene of the Working Environment," "Do Good Working Conditions Pay?" and "Special Subjects." Dr. Heiser begins by quoting the standards of the American College of Surgeons for industrial medical service, and proceeds to illustrate how

the small plant can set up a health program, applying the standards. He provides a good summary of modern industrial preventive and therapeutic practices with proper emphasis in the former on health education, nutrition, and mental hygiene. Atmospheric, sanitary, and safety engineering are each given attention as part of the hygiene of the environment. Women in industry, absenteeism, recreation and morale, and rehabilitation are discussed in the special subjects section. A check list of industrial health practices is included for purposes of self-appraisal.

FREE NATIONAL SAFETY COUNCIL PUBLICATIONS OF SPECIAL INTEREST

TO PUBLIC HEALTH WORKERS

Safe at Home. A 24 page booklet on home accident hazards. Current edition issued in January, 1943.

Fight the Axis in Your Home. Brief, bright and snappy home safety leaflet. Published, Spring, 1943.

He's Afraid of the Man With the Hoe. Four page farm safety leaflet. Published, Spring, 1943.

Home and Farm Safety Guides. Single sheets of safety information on 56 home and farm operations. Prepared during the period January through November, 1943.

MALARIA CONTROL DRAINAGE

IN MISSISSIPPI

The Mississippi State Board of Health has published a brochure called "Malaria Control Drainage, A Guide to the Public Health Worker, Landowner, Farmer, City Official, County Supervisor, and Others Interested, Containing the Answers to Many Fundamental Questions on Minor Drainage." This is a well illustrated handbook prepared for the use of persons without full technical equipment in the field of drainage and, as Dr. Felix J. Underwood, the Executive Officer of the State Board of Health, remarks, the material

should have a wide application throughout the southeastern United States. The combination between good typography, good illustration, and a lucid text is indeed commendable.

LEAD POISONING AND BENJAMIN

FRANKLIN

In December, a report of the Committee on Lead Poisoning of the Industrial Hygiene Section was published. "Occupational Lead Exposure and Lead Poisoning" it is titled, and, according to the Lead Industries Association and other reviewers, "thoroughly summarizes present-day knowledge" in regard to the recognition, control, diagnosis, and treatment of industrial lead poisoning. Present-day knowledge adds up to quite a lot, even to the conclusion that "recovery from lead poisoning is usually complete, leaving no partial or complete disability," and reminds us that this generation again is the beneficiary of centuries of patient observation, deduction, and reasoning fused into another weapon for our use in preventing and alleviating human misery.

Benjamin Franklin was a pioneer in the diagnosis of lead poisoning. In 1768, he wrote to Cadwallader Evans that he had long believed the disease to be due "to a metallic cause only; observing that it affects, among tradesmen, those that use lead, however different their trades; as glaziers, letter founders, plumbers, potters, white-lead makers and painters." Drawing on his own background as a printer, Franklin expressed in another letter the belief that lead poisoning among typesetters was due to the particles of metal swallowed with their food by slovenly workers who ate their meals without washing their hands. "The presence of vapors, or fumes, or fine dust of lead compounds in the air breathed by workmen is the most important factor in occupational lead exposure," says the new

Report, "however, lead compounds which contaminate the hands, food, tobacco, or other objects taken into the the mouth, may not be ignored as means of exposure, even though the conditions be such that these compounds are not disseminated into the air breathed by men."

COMMUNICABLE DISEASE REGULATIONS
OF THE IOWA STATE HEALTH
DEPARTMENT

The new volume of *1943 Rules and Regulations for the Iowa State Department of Health Relating to Communicable and Other Reportable Diseases* has been received. This volume is notable among those of similar nature published by state departments of health. Among other features, there is included a graphic chart showing the course of various reports required of physicians and others in the state of Iowa.

Section XV on the Control of Communicable Diseases incorporates the American Public Health Association's report on this subject, which is official with the Association and with the U. S. Public Health Service. While it is not unusual for this report to be approved in principle by state departments of health as a guide for the control of communicable disease, this is, so far as known, the only instance in which this report has been included verbatim as a section in the regulations, together with the introductory material. In spite of the fact that this A.P.H.A. report was not set up in the usual form for regulations in a state department of health, it lends itself rather well to this use.

Section XIII of the regulations on the closing of schools represents a forthright attempt to state the circumstances surrounding this measure and, because of certain unique features, is hereby quoted in full.

"On the outbreak of an epidemic, there is often a popular demand that the schools be

closed. This is based upon the belief that infection may spread among the children in attendance. It is noteworthy, however, that health authorities and the Rules and Regulations of state departments of health in general omit any recommendations that schools be closed. The reasons for this are:

"(1) Children in schools are under more careful disciplinary control than they are in their homes. With effective supervision by the health officer and with the aid of a trained and experienced community nurse, in coöperation with school officials and the pupils themselves, the children are safer at school than outside.

"(2) Closure of schools is futile, unless all susceptible children are forbidden to leave their own yards. Permitting them to roam the streets, to attend the moving picture theatres, churches, social gatherings, or to indulge in unsupervised group play, may be much more dangerous from the standpoint of interchanging infection, than if they were under the discipline of the schoolroom.

"(3) Past experience has shown that the mere closing of schools has had little or no effect upon the progress of epidemic diseases. Unless, therefore, a community is prepared to declare a complete and rigid embargo upon all susceptible children of school age, isolating them universally to the limit of their own yards and absolutely forbidding them to play with children of other families, the SCHOOLS, ordinarily, SHOULD NOT BE CLOSED.

"(4) School boards, parent-teacher groups and other sponsoring agencies should concentrate on such efforts, year by year, as will assure immunity of children against diphtheria, smallpox, and other infectious diseases for which specific preventive measures are available.

"Parents are urged to confer with the attending physician and to have children immunized against preventable diseases early in life."

The Iowa State Department of Health and Dr. Walter L. Bierring, Commissioner, are to be congratulated on the format and the contents of this report.

BALTIMORE'S HEALTH SERVICE 150
YEARS OLD

One need not be an antiquarian to enjoy the December, 1943, issue of *Baltimore Health News*. Dr. Huntington Williams and his staff have selected

some excellent historical landmarks and the photostatic and photographic reproductions of original documents point up the record in a unique fashion. This humanizes history so all may enjoy it.

SMALLPOX PREVALENCE AND COMPULSORY VACCINATION

Considerable interest has been expressed in a study made by Franklin H. Top, M.D., and Laura E. Peck, R.N., entitled "A Small Outbreak of Smallpox in Detroit" (published in the May, 1943, issue, *A.J.P.H.*), in which the prevalence of smallpox has been correlated with the type of regulation enforced in each of the states relating to vaccination.

Health educators who are seeking to promote an interest in vaccination will wish in this connection to read the article by Brock C. Hampton of the U. S. Public Health Service on Smallpox in Relation to State Vaccination Laws and Regulations (*Public Health Reports*, Vol. 58, No. 49, December 3, 1943, pages 1771-1777).

The regular increase in the rate of smallpox prevalence in five groups of states selected according to the type of vaccination regulation, prompts the author to conclude: "The difference in the incidence of smallpox in the different areas of the United States is apparently related to the various provisions of law or regulation, especially with reference to the requirement of vaccination as a prerequisite to school attendance; it is apparent that smallpox is lowest in those jurisdictions which have some type of universal vaccination requirement."

UNION COÖPERATION IN CALIFORNIA

Reporting on the year's activities of the California Social Hygiene Association, Leo Arnstein, Executive Secretary, has called attention to several instances where union officials are exercising

effective leadership in urging their members to have blood tests. The California State Federation of Labor by resolution is calling upon all unions to have new members blood tested on entering the union. Management, Mr. Arnstein states, has been surprised to discover the enthusiasm with which the unions have responded in plant-wide campaigns. In some cases, not only were the blood tests accepted with alacrity, but the unions also asked for chest x-rays for all their members. Seventy-five to 85 per cent of union members have been given blood tests in certain industries. This attitude on the part of California's unions could not have been established without good health education and good public relations by Mr. Arnstein's organization and the state and local health departments and agencies.

PRO AND CON OF WAGNER-MURRAY- DINGELL BILL (S-1161)

The public health profession has had access to numerous reviews of the provisions of Senate Bill 1161 proposed by Senator Wagner and his associates. Publications of the American Medical Association have carried critical analyses of the Bill and a review of public reactions to it.

Among relatively few reviews of the medical features of this Bill which are fundamentally favorable to the Bill may be cited the report dated December 30 of the Committee of Physicians for the Improvement of Medical Care, Inc. John B. Peters, M.D., is the Secretary in New Haven, Conn. Among other recommendations in this report is the proposal that it would be wiser to include at the start a smaller proportion of the population than the coverage of between 100 and 110,000,000 persons. Means are suggested for accomplishing this purpose. "Under a tax-supported system it would be possible to develop a program logically to

provide care first for those who lack it most, the truly needy, expanding it progressively to cover the whole population, either according to a prearranged time schedule or as experience and expediency warranted its extension."

The report points out that there is an ever-growing and wholesome tendency for hospitals and out-patient clinics to function as community health centers. A well organized and highly developed out-patient service, according to the report, is probably the finest existing example of the advantage of group medicine. The report recommends the development of such coördinated community services about a hospital. This will tend to prevent the unnecessary hospitalizing of patients for conditions that do not require in-patient facilities.

Health workers seeking to familiarize themselves with both sides of the current discussion will find the report stimulating. A copy can be obtained from Dr. Peters at 789 Howard Avenue, New Haven, Conn.

WORTH ACQUIRING

"The Medical Social Worker in a Public Health Department," published by the Bureau of Medical Social Service of the Los Angeles County Health Department, H. O. Swartout, M.D., Dr.P.H., County Health Officer. A series of three papers on the function of the medical social worker in the tuberculosis, social hygiene, and maternal health programs of a county health department.

"Approved Films on Food and Nutrition, 1944," a Selective Catalogue, published by the Committee on Evaluation of Motion Pictures, New York City Food and Nutrition Program, 45 Lafayette Street, New York 13, N. Y. (25¢.) This is the second list prepared by the committee, and summarizes and appraises 46 films. Full information with regard to producer, distributor, and terms of use is given

for each. The committee acknowledges the coöperation and technical advice of Adolf Nichtenhauser, M.D., of the American Film Center, Inc., in the preliminary preparation of many of the film reports.

The December issue of "Tic," published by Ticonium, 413 North Pearl Street, Albany, N. Y. Contains a tabular review of selected prepayment plans for medical care sponsored by component groups of the American Medical Association, and a tabular summation of the Social Security Act and recently proposed amendments; also a description of the health education program of the American Dental Association and comments on the Wagner-Murray-Dingell Bill (S. 1161) from the dentist's standpoint, by Harry Strusser, D.D.S.

"Borden's Review of Nutrition Research" for December, published by The Borden Company, 350 Madison Avenue, New York 17, N. Y., devoted to "Nutrition and Vision-Vitamin A." "The relation of Vitamin A to the visual cycle is of more than academic or scientific interest. Its importance in night driving, in night flying and in general vision in subdued light . . . are strong and cogent reasons for the inclusion of optimum amounts of this vitamin in the diet."

"Penicillin, Merck, Its Actions and Uses," 24 page booklet with full color illustrations on the discovery, production, pharmacology, clinical indications, dosage and administration of penicillin, with a bibliography of 100 items. Published by Merck & Company, Inc., Manufacturing Chemists, Rahway, N. J. Incidentally, correct pronunciation of the name of this drug accents the third, not the second syllable, radio announcers to the contrary notwithstanding.

Series No. 7 of the Industrial Bulletin Board posters, published by the National Tuberculosis Association and distributed through state and local tuberculosis associations. There are

four posters in the series: "Stay home when you have a cold," "Don't spit!" "Germs hate soap," and "A full night's sleep makes you fit for a full day's

work!" Materials on personal cleanliness and good health manners are in demand and these should be distinctly useful.

Venereal Disease Laws

Excellent progress was made during 1943 in the enactment by state legislatures of premarital, prenatal, prostitution and venereal disease control laws and amendments, Dr. Walter Clarke, Executive Director of the American Social Hygiene Association, said in announcing the results of a legislative survey just completed by the Association's Division of Legal and Protective Services.

"These various laws have the purposes either of protecting mothers and babies against syphilis, of enabling communities to take effective steps in the repression of prostitution, or of facilitating the finding, reporting, treatment and quarantine of infectious venereal diseases. It is encouraging that such solid progress has been made in this field even in the midst of war. Experience has proved that such legislation is an essential factor in maintaining a sound, smoothly functioning venereal disease control program."

The Association's survey shows that during 1943 the following social hygiene legislation was passed:

In Alabama a unique law was adopted which requires all inhabitants of the state between the ages of 14 and 50 to have an approved blood test for syphilis. An appropriation of \$75,000 was provided to carry out provisions of the law.

The States of Indiana, Nebraska, Missouri, and Wyoming passed premarital examination laws requiring ex-

amination by the physician of both applicants for a marriage license including a blood test for syphilis as a prerequisite for a marriage license. Idaho, Georgia, Kansas, and Nebraska adopted prenatal examination laws for syphilis. This means that there are now 30 states which have premarital laws for the protection of marriage from syphilis and 30 states which have prenatal laws protecting babies from syphilis. The first premarital examination law was passed in May, 1935, by Connecticut, and the States of New York and Rhode Island enacted the first prenatal examination laws in 1938.

Arkansas, Florida, Georgia, Oklahoma, Tennessee, Texas, and West Virginia adopted new laws for the repression of prostitution, making a total of 19 states which now have adequate legislation against most of the aspects of prostitution. Ten other states have good legislation against prostitution with the exception of those provisions concerning the activities of customers of prostitutes.

The following states strengthened their venereal disease control laws, particularly in relation to the reporting, treatment, quarantine, follow-up, and finding of persons with an infectious venereal disease: Connecticut, Florida, Indiana, Maine, Maryland, Montana, New Mexico, North Dakota, Oklahoma, Oregon, Tennessee, Vermont, and West Virginia.

The premarital examination laws of

California, Connecticut, Illinois, Iowa, Massachusetts, and Vermont were amended by the legislatures to obtain more smooth operation. An interesting feature of the Massachusetts premarital law, as amended, permits marriage of applicants under certain conditions even though one or both may have syphilis in an infectious stage. The physician who discovers evidence of syphilis must inform both applicants to the marriage of the evidence and nature of such disease.

Two laws of special interest in this field were passed by the Florida legislature. One permits the revocation of a license of a boarding house, rooming house, hotel, and restaurant for any

violation of the laws against prostitution, lewdness or assignation. The second statute requires all persons rejected or deferred from military service who are infected with venereal disease to report to the venereal disease clinics operated by the Florida State Board of Health or to take treatment from a private physician or at public expense.

In Oklahoma, the Governor signed H.B. 37 on March 18, 1943, relating to the examination and treatment of persons confined in public or private institutions, or any person arrested by lawful warrant for vagrancy, prostitution or other sex crimes for the purpose of determining if they are infected with syphilis or gonorrhea.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Criminal Careers in Retrospect—
By Sheldon and Eleanor Glueck. New York: Commonwealth Fund, 1943. 384 pp. Price, \$3.50.

The struggle of the aspiring theoretical science of criminology to achieve recognition among the applied sciences is yielding results, as exemplified in this volume by Harvard University's distinguished criminologists. It is the fruitage of a system of careful research and objective reporting that has only few contemporary rivals in any field.

The Gluecks commenced an intensive study of 510 adolescent offenders a little more than 15 years ago. The first two volumes (*Five Hundred Criminal Careers* and *Later Criminal Careers*) in the trilogy that comprises their report on these offenders spanned the two 5 year periods following the expiration of their sentences to the Massachusetts Reformatory, a congregate penal institution. This volume reports the follow-up on those careers in the last 5 year period.

During the last period as many as 439 of the original 510 were located, and they were subjected to a painstaking study of their traits, characteristics, and, among other aspects of their personalities and habits before and after they resumed life in a free world, of their contact with welfare and law enforcement agencies. The authors' object in assembling this material was to examine the nature of the offenders' behavior against the differentiated backgrounds thus revealed. A large percentage remained in the criminal ranks; a similarly large portion of the surviving group were re-arrested for other offenses, convicted, and again institu-

tionalized. A relatively small group refrained from antisocial behavior.

Why did so many fail to respond favorably to traditional forms of peno-correctional treatment? Why did some reform and others not? What combination of characteristics conspires to prevent the emergence of law abidingness from anti-sociality despite punitive treatment?

These were the crucial questions with which the authors, patiently and fastidiously searching in this difficult field, were concerned. And it was to these questions that they sought answers of sufficient tested validity to justify the construction of prognostic devices (prediction tables) which might become utilizable in the delicate process of judging and treating differently constituted youthful offenders. The Gluecks caution us that their tables are experimental; indeed, their thoroughly scientific attitude toward the problem would justify no other approach. However, upon the basis of a meticulous investigation of environmental circumstances, family relations, economic responsibilities, work, use of leisure, and criminal conduct of a substantial group of such offenders, the authors believe that many factors in criminal behavior hitherto regarded as imponderables become more clearly defined; the presence of certain traits and characteristics in offenders militates against reformation except under versatile forms of social control; elements in the social, economic, and psychological histories of those engaged in criminality take on new significance when related to treatment procedures designed to fit the offender rather than the offense.

Those interested in the administration of criminal justice and in the elimination of ancient trappings in its peno-correctional system should discover here material infinitely helpful in the creation of reforms. Those who have undertaken the task of functioning in the preventive field would here be given useful tools with which to do their work.

EDWIN J. LUCAS

Collected Reprints of the Grantees of the National Foundation for Infantile Paralysis—Vol. III. *New York: National Foundation for Infantile Paralysis, 1943.* 978 pp.

This volume consists of collected reprints of grantees of the National Foundation for Infantile Paralysis and covers roughly the period from September, 1941, through December, 1942. Although the subject matter of these reprints deals with poliomyelitis, the phases studied and reported cover many fields, such as anatomy, physiology, virology, clinical aspects, and the like. The volume does not lend itself for review purposes. For those workers specializing in public health and allied sciences, who are interested in poliomyelitis, it serves as a convenient means of keeping together a large number of papers on the subject. However, all papers on poliomyelitis are not included in this volume. There are both author and subject indexes.

FRANKLIN H. TOP

Clinical Diagnosis by Laboratory Examinations—By John A. Kolmer. *New York: Appleton-Century, 1943.* 1239 pp. Price, \$10.00.

The primary purpose of this book is to present the applications and interpretations of laboratory tests used in clinical diagnosis. While a section of some 130 pages of the book is devoted to methodology of the simpler and more frequently employed procedures, it is relatively brief and is intended chiefly

for illustrative and teaching purposes. The author has deliberately avoided an exhaustive professional laboratory manual. He has however, given instructions and precautions concerning the collection and preparation of blood samples, spinal fluid, cultures, etc., for various laboratory tests, including such details as the use of para-aminobenzoic acid in blood cultures of individuals receiving sulfonamide therapy, and several essential but all-too-often overlooked precautions regarding the avoidance of preservatives and procedures which interfere with, or completely invalidate, laboratory tests. Throughout the book physiological and pathological processes are discussed rather fully as the basis for interpreting results of laboratory findings; and various findings themselves are discussed in relation to the underlying principles of physiology and pathology. The style is remarkably concise and the information generally complete and authentic. There are some relatively minor errors and omissions, such as failure to mention monkey inoculations for diagnosis in yellow fever, although susceptibility of the monkey is mentioned. Statements concerning the rôle of *Staphylococcus aureus* in food infections, as distinct from food poisoning might arouse some controversy.

There are good discussions of the significance of various cytological and chemical findings in normal and pathological blood, and analogous descriptions of urine chemistry and microscopy, examinations of various other body fluids and exudates, toxicological tests, parasitological, mycological and bacteriological examinations, the hyper- and hypo- vitaminoses, endocrinology, etc. A section on intradermal tests includes several color plates of skin reactions. Most of these are excellent but those of the Schick test do not convey a very accurate idea of the pigment and scaling characteristic of the reac-

tion. The general applicability of the picture of the 24 hour reading on the Mantoux test might be questioned. The author correctly states that Mantoux readings should be made at least 48 hours after injection and are best judged by the amount of edema. In general the other illustrations, of which there are unfortunately less than 100, are well selected and of definite help. The inclusion of over 130 condensed tables containing summaries and data classified in relation to various pathological conditions, clinical problems, interpretations of laboratory data, possible sources of error, differential diagnoses, etc., should prove of inestimable value to students and to hurried practitioners. An extensive index adds greatly to the usefulness of the volume, as does the large table of contents, the latter covering some 32 pages. The 3 page introduction is particularly stimulating. The printing, editing, and binding are in the usual excellent style of the publishers. This volume will be of real value on any laboratory or office reference shelf.

MARTIN FROBISHER, JR.

Synopsis of Tropical Medicine—
By Sir Philip Manson-Bahr. Baltimore: Williams & Wilkins, 1943. 224 pp. Price, \$2.50.

The question of whether medical synopses ought to be encouraged has never been answered satisfactorily. The answer is probably that, if they are used by the right people for the right purpose and if the subject is a suitable one for compression, they have their place in medical literature. Sir Philip Manson-Bahr is one of our leading exponents of tropical medicine and the author of what is almost certainly the best single-volume textbook on tropical disease. Never has so much been compressed into so little so skillfully, as in his synopsis. Yet, the reviewer is even more than ever convinced that tropical

medicine is not one of those subjects that lend themselves to this form of treatment. He is equally convinced that the book is not the ideal one for the medical officer in the Armed Forces, for whom it is avowedly written, unless this officer has already had a firm founding in tropical medicine and parasitology; in this case he will find it a very useful memory reviver. What this officer requires is not the disconnected highlights on symptomatology, parasitology, and treatment of innumerable tropical diseases, only a fraction of which he will be likely to encounter, but a handbook in the principles of malariology and tropical hygiene.

Nevertheless, the book does constitute a useful addition to the literature on tropical diseases, and will be prized and referred to frequently by those with a good knowledge of the basic principles of the subject, but who need certain specific data quickly. The bold captions make rapid reference easy, and, with few exceptions, the information given is accurate.

One cannot help admiring the comprehensiveness of each section. Very little of importance in the parasitology, symptomatology, diagnosis, and treatment has been omitted, and the range of subjects discussed is a very wide one; it includes all important tropical diseases, and most minor ones.

There are two general criticisms. The first is that the practical public health point of view is seldom faced; to suggest as a preventive measure for hookworm infection that "labourers . . . should wear well fitting boots and take antiseptic footbaths of 3 per cent salicylic acid in *ethyl alcohol*" may be sound advice when it is given in a consulting room in Harley Street, but it is scarcely a practical solution to the problem of the millions of hookworm sufferers in poor eastern countries. The second is that, to Sir Philip, pathology usually means little more than post-

mortem morbid anatomy, which is, to say the least, a pessimistic attitude.

Two special criticisms will suffice; the omission of tetrachlor-ethylene, probably the drug of choice for the treatment of ancylostomiasis, must have been an oversight, but it is an unfortunate one, and the recommendation to give "2 grammes of typarsamide *thrice* weekly" seems dangerous.

It is not humanly possible to write a book that pleases everybody, but despite the intrinsic and incidental defects of this book, the reviewer does not believe that any living man could have written a better synopsis of tropical medicine. L. EVERARD NAPIER

Curriculum Problems in Health and Physical Education—By *Vaughn S. Blanchard*. New York: Barnes, 1942. 128 pp. Price, \$1.50.

Health education and physical education in public schools now are undergoing changes which will help them to meet more effectively the needs and interests of children and youths. In making these changes it is important that teachers recognize the social and economic problems of the communities in which children live and the effect of these conditions of children. This point of view is well developed in *Curriculum Problems in Health and Physical Education*.

Following a discussion of the relationship of programs of health and physical education to varying concepts of the purposes and objectives of education, principles for guiding the construction of a curriculum are presented. The interests of children, their needs, racial factors, and environmental conditions are considered, as well as the importance of administrative provisions which make healthful living at school possible. Particular emphasis is placed on the curriculum for physical education.

For the help of those engaged in cur-

riculum construction suggestions are offered for the preparation of units and for a curriculum developing organization which makes use of the entire teaching personnel of a school.

This book deserves the attention of those concerned with problems of curriculum construction in health and physical education.

CHARLES C. WILSON

Children's Centers—A Guide for Those Who Care for and about Young Children—Edited by *Rose Alschuler*. Issued by the National Commission for Young Children. New York: Morrow, 1942. 168 pp. Price, \$1.50.

This is a timely book—replete with valuable data and specific information helpful to those planning, setting up, or supervising any type of unit for young children. The material is well organized and eminently practical. It contains an illustrated equipment list and an excellent bibliography. This small, compact, convenient book covers the most important aspects of the field with wide perspective, understanding, and sound, useful advice.

Children Can Help Themselves—By *Marion Olive Lerrigo*. New York: Macmillan, 1943. 219 pp. Price, \$2.25.

This book would be particularly helpful in families where there is an only child, or with the first child in a family. It is written primarily for parents, giving close-up details of the everyday life of a child from the age of one month to eleven years of age.

It gives parents a perspective of how most normal, healthy babies develop. Knowing what to expect of a healthy child at any given age helps to relieve parent anxiety and to keep a balance between our over-cautious and our too careless attitudes.

Written for the layman in simple, narrative form, in chronological style,

it interests only those who are living in a day-by-day relationship with children. The earliest months of infancy are most fully considered, with a far more cursory attitude toward the older child. To find a sensible and casual, yet wise and sympathetic attitude toward a child's habits in relation to the toilet, eating, and sleeping is gratifying.

Your Child, His Family and Friends—By Frances Bruce Strain. *New York: Appleton-Century*, 1943. 210 pp. Price, \$2.00.

In dealing with the feeling aspects of a child's development an attempt is made to help the adult to recall the emotional atmosphere of his own childhood and thereby gain the much needed insight into the emotional life of a child. Mrs. Strain stresses the importance of the early developmental years in every child's life, as conditioning his approach to all that he encounters in his later life.

Our Children Face War—By Anna W. M. Wolf. *New York: Houghton Mifflin*, 1942. 214 pp. Price, \$2.00.

Mrs. Wolf, well known through her association with the Child Study Association in New York City, writes out of a rich background of experience with parents and with children. Her consideration of the effects of this war on our children gives us pause. She thinks of children sensitively and with vision.

CORNELIA GOLDSMITH

Vitamins and Hormones—*Advances in Research and Application. Vol. I*—Edited by Robert S. Harris and Kenneth V. Thimann. *New York: Academic Press Inc. Publishers*, 1943. 452 pp. Price, \$6.50.

This volume is not divided into chapters but is made up of ten sections, each one dealing with a special subject written by investigators who are recognized authorities in the fields they discuss. Thus the subject of Choline is discussed by Best and Lucas; the ap-

praisal of nutritional states by Jolliffe and Most; physical methods for the identification and assay of vitamins and hormones by Loofbourow; the chemical and physiological relationship between vitamins and amino acids by Mitchell; the photoreceptor function of the Carotenoids and Vitamin A by Wald; the significance of the vitamin content of tissues by Roger Williams; growth factors for protozoa by Hall; physiology of pernicious anemia material by Minot and Strauss; the intermediate metabolism of the sex hormones by Pincus and Pearlman; and the Hormones of the adrenal cortex by Reichstein and Shoppee.

It is the plan of the editors to publish yearly volumes on Vitamins and Hormones which will chronicle progress and point the way to new achievements. This volume, since it is intended primarily as a reference book, contains a very complete subject and author index. It has been the aim of each author to accumulate, correlate, and digest the current literature in the field in which he is interested, to point out where knowledge is incomplete, and to indicate the directions in which future research would be most fruitful.

The reviewer agrees with Dr. McCollum, the author of the Foreword, when he states "The time is ripe for the founding of such a venture, since it is no longer possible for anyone to read sufficient of the current papers and the library files dealing with these two classes of substances to assimilate all the knowledge which has accumulated. We must increasingly depend upon our colleagues, who maintain mastery of specialized experimentation, to appraise for us the numerous contributions which they alone can interpret, sifting error from truth and assembling scattered data to make a connected account which places a body of related facts in proper perspective."

This function of the new publication

is well fulfilled. No research worker who wishes to keep himself properly oriented in his field and no individual who wishes to keep abreast of these specialized subjects can well be without this volume. IRA A. MANVILLE

Air-borne Infections—By *Dwight O'Hara, M.D.* *New York: Commonwealth Fund, 1943.* 114 pp. Price, \$1.50.

In this group of essays Dr. O'Hara reviews the biology of air-borne infections. The central theme is that air-borne infections share a characteristically decreasing death rate which is greater than we can possibly claim as due to our measures for their direct control. With full appreciation of host-parasite relationship, Dr. O'Hara emphasizes the tremendous importance of inapparent infection, and warns that complete elimination of infection will result in a very vulnerable population unless artificial active immunization can be substituted. This broad perspective is achieved by means of excellent clinical discussions of individual respiratory diseases, supported by a minimal number of appropriate charts and tables. The significance of social and environmental factors is brought into focus and the whole is imbued with admirable preventive flavor. Each discussion is authoritative and as up-to-date in its scientific allusions as in its sprightly phraseology. The style is witty and charming, the ideas are provocative. This is a booklet recommended to everyone. Even the price is right! CHARLES EDWARD SMITH

Personal and Community Health—By *C. E. Turner, Sc.D., Dr.P.H.* (7th ed.) *St. Louis: Mosby, 1943.* 585 pp. Price, \$3.50.

This seventh edition of Turner's standard textbook on personal and community health has the virtues of previous editions and the additional value

of the author's added experience and suggestions he has received from those who have used the previous editions.

It is divided into two parts, dealing respectively with personal health and with community health. There is an extensive appendix dealing with the control of communicable diseases and another with disinfection. There is a list of prefixes, suffixes, and combining forms, a glossary and an excellent index.

In Part I are 19 chapters dealing with introductory material on hygiene and health, nutrition, digestion, oral hygiene, respiration, circulation, kidneys, skin, endocrines, sense organs, nervous system, mental hygiene, body activity, body mechanics, foot hygiene, reproduction, heredity, narcotics and stimulants, and a summarizing chapter on adult hygiene.

Part II contains 12 chapters on community health, dealing respectively with the science of disease prevention, communicable diseases, essential facts of immunity, three great plagues (tuberculosis, syphilis, and the common cold), food control, water supply, waste disposal, ventilation, heating and lighting, public health administration, maternal and child hygiene, and school and industrial hygiene.

The material is factually sound, conservative, and dependable. It is, in the judgment of this reviewer, more attractively presented than in previous editions. An attractive quality of the presentation is the number, diversity, and quality of the illustrations and the clear typography, especially the generous leading between the lines. Even where small type is used it is readily readable.

This is a book that for accuracy, comprehensiveness and objectiveness may safely be recommended to any teacher or student as a reference work.

The four color plates are a distinct addition to the book.

W. W. BAUER

- EDUCATORS INDEX OF FREE MATERIALS. By John Guy Fowlkes. Randolph, Wisc.: Educators Progress League, 1943. 165 pp.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Public Health in England—After four years of war the health of the English has not only not deteriorated but in some respects has improved, reports the Ministry of Health: 1942 was a year of record breaking statistics with lowest maternal and infant mortality rates, and standardized civilian death rates. Surveys were made which indicated that people were trying to keep fit. On the other hand, the incidence of lousiness is high, many people still sleep in their daytime underwear or in unventilated rooms and old wives tales still are believed. Health education is stressed but more needs to be done.

ANON. On the State of the Public Health. *J. Roy. Inst. Pub. Health & Hyg.* 6, 11:287 (Nov.), 1943.

Sanitary Code—Third edition of the Sanitation Code intended for state and local adoption.

ANON. Emergency Minimum Sanitation Standards. *Pub. Health Rep.* 58, 50:1795 (Dec. 10), 1943.

"Shipyard Eye" a Misnomer—If you have shared the popular opinion that epidemic keratoconjunctivitis is a brand new disease this article will disabuse your mind. Also it was not epidemic in Gulf or Atlantic Coast shipyards. To infer that the outbreak spread from Hawaii across the continental United States is not warranted by the facts. Seems as though you had better read the article whatever your beliefs may have been.

BEDELL, A. J. Distribution of Epidemic Keratoconjunctivitis in the United States. *J.A.M.A.* 123, 17:1107 (Dec. 25), 1943.

"Treated Colds Showed No Striking Difference"—As a result of this study, conclude three men whose

opinions all will respect, we are opposed to the routine use of sulfonamides in the treatment of the common cold.

CECIL, R. L., *et al.* Sulfadiazine in the Treatment of the Common Cold. *J.A.M.A.* 124, 1:8 (Jan. 1), 1944.

Good for American Heads, Too—Rural public health nurses may be interested in this formula which was used in a big way on lousy heads in Mexico. A doctor in New York found it just as efficacious in that city. The formula includes phenyl cellosolve, ethanol, and methyl salicylate.

DAVIS, W. A. A Treatment for Pediculosis Capitis. *J.A.M.A.* 123, 13:825 (Nov. 27), 1943.

Smallpox a la mode—Where vaccination is required, there smallpox incidence is lowest. None of us expects that this fact will have any influence upon the alleged reasoning of the rabid antivaccinationist, but it is a useful statistic to have tucked away none the less.

HAMPTON, B. C. Smallpox in Relation to State Vaccination Laws and Regulations. *Pub. Health Rep.* 58, 49:1771 (Dec. 3), 1943.

Community Studies of Tuberculous Selectees—In this study of inductees infected with tuberculosis there is found evidence that socio-economic level and nationality are secondary to population density as factors influencing the rate. There is need for further investigation along these lines say the authors of this excellent research.

HYDE, R. W., and ZACKS, D. Socio-economic Aspects of Disease. *New England J. Med.* 229, 22:811 (Nov. 25), 1943.

Pep, Kick, Crackels, *et al.*—As an aid to health workers interested in the

nutritive values of prepared cereal foods, the Council on Foods and Nutrition has obtained factual information about the amounts of thiamine, riboflavin, and niacin in readily obtainable products. Table tells all.

KITZES, G., and ELVEHJEM, C. A. Vitamin Content of Prepared Cereal Foods. J.A.M.A. 123, 14:902 (Dec. 4), 1943.

Into the Mouths of Babes—Two quadrants of the teeth of a group of children were treated with 7–15 topical applications of sodium fluoride. Dental examinations were made before and a year after on these and a control group of children. Approximately 40 per cent less new carious teeth occurred in the treated than the untreated portions of the mouths, the reduction being greater in the upper than the lower quadrants. Teeth previously attacked by caries were not influenced by the treatment. In the untreated quadrants the incidence of caries was the same as in the mouths of the control group.

KNUTSON, J. W., and ARMSTRONG, W. D. The Effect of Topically Applied Sodium Fluoride on Dental Caries Experience. Pub. Health Rep. 58, 47:1701 (Nov. 19), 1943.

Better Late Than Never—Experience at the Guggenheim Dental Clinic gives evidence that sound habits instilled at baby clinics give but transient results, for the baby's routine is soon made to fit the family activities bringing on increasing irregularities in meals, sleep, essential foods, and general daily care. Only a few children have the minimum allotment of milk. School dental services are the logical solution to the problems created by this condition, concludes the writer.

KRASNOW, FRANCES, PH.D. Dental Caries:

A Serious Health Problem. J. School Health. 13:239 (Dec.), 1943.

Apropos "Are Council and Board Members People?"*—A lot of unpleasant data are presented which reveal no basis for supposing that important creative work is being done today by individuals who are older than like contributors of past centuries have been. Indeed, the change seems more in favor of our present crop of younger smart-alecks than in the direction of us stalwarts—with our hardened arteries. Yes, the findings hold for medicine and public hygiene as well as literature and philosophy. Humpf! say we.

LEHMAN, H. C., Man's Most Creative Years: Then and Now. Science. 98, 2549: 393 (Nov. 5), 1943.

* Editorial A.J.P.H. 33, 9:1126 (Sept.), 1943.

Lo! The Poor Indian—An isolated colony of Indians living along the path of the Alaska Highway had, in succession, tribe-wide epidemics of measles, dysentery, jaundice, German measles, whooping cough, and meningitis. None of these outbreaks returned to plague the white population from which it sprang.

MARCHAND, J. F. Tribal Epidemics in the Yukon. J.A.M.A. 123, 16:1019 (Dec. 18), 1943.

Measles Prophylaxis—Measles virus cultivated upon chick embryo produced measles of a mild character in 80 per cent of known susceptible children. There is evidence that the mild disease affords some protection against natural infection.

RAKE, G. Experimental Investigation of Measles. J. Pediat. 23, 4:376 (Oct.), 1943.

ASSOCIATION NEWS

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

William J. Faulkner, M.D., D.P.H., 700 W. Tenth St., Jacksonville, Fla., P.A. Surgeon, U. S. Public Health Service

Pedro Hernandez del Valle, M.D., Box 121, Isabela, Puerto Rico, Medical Officer, Insular Health Dept.

Miriam Hubbell, M.D., Imperial County Health Dept., El Centro, Calif., Health Officer

Jesus M. Rodriguez, M.D., Dept. of Health, Adjuntas, Puerto Rico, Medical Officer

Catherine W. R. Smith, M.D., Washington County Health Dept., Abingdon, Va., Health Officer, Smyth-Washington-Bristol Health Dist.

Dr. Arsenio Vallecillo, De Diego 37, Esq. Travieso, Santurce, Puerto Rico, District Supervising Medical Officer

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

Wanted: A physician trained in tuberculosis to assume administrative control of the Bureau of Tuberculosis in an eastern city of 200,000 population. Salary \$3,900-\$4,500 plus cost of living adjustment. Address Box B, Employment Service, A.P.H.A.

Sanitarian wanted: Preferably with Bachelor's degree or engineering degree, plus public health experience or training. Must have own car. Applicant with lower qualifications will be offered an opportunity to take a short, free indoctrination course. Salary \$1,920 per year with travel allowance of \$50 per month, if qualified. Apply Dist. Dept. of Health, No. 6, Central Office, Newberry, Mich., Dr. Franklin.

Wanted: Pediatrician to supervise medical care of children at cerebral palsy center being established by private institution in cooperation with Illinois Division of Services for Crippled Children. Salary commensurate with experience and training. For further information write Lawrence J. Linck, Director, Division of Services for Crippled Children, 1105 So. Sixth St., Springfield, Ill.

The Department of Health, New Jersey, whose industrial health activities

have expanded rapidly during the present war, has announced its need for two full-time industrial hygiene physicians for its Industrial Hygiene Service. As one of the leading states in the production of war materials, New Jersey offers unusual opportunities for gaining experience in occupational disease control besides giving the physician a chance to make a valuable contribution to the war effort. The principal duties of the selected physicians will be consultations in regard to the following: control of occupational diseases; industrial toxicological problems; evaluation of adequacy of plant medical services; promotion of measures which will reduce absenteeism from non-occupational causes; and conduct of industrial health education activities. Physicians interested in these positions should write to the Department of Health, Trenton, N. J.

Merit System for Personnel Administration in Delaware will set examinations for 3 positions in the Delaware State Board of Health shortly. The positions open for examination, together with the beginning salaries, are: Deputy State (County) Health Officer (\$3,800), Pediatrician (\$3,600), and Medical Social Consultant (\$2,400).

These examinations will be unassembled.

bled, but successful candidates will be expected to appear in Delaware for an oral interview which will be a weighted part of the examination. Appointments may be expected soon after the examinations are conducted.

Information and specifications as prepared for each position may be secured by communication with the Merit System Supervisor, P. O. Box 1911, Wilmington, Del., and application for examination must be made on the official form.

The Milwaukee Health Department is interested in obtaining an instructor in hospital nursing to conduct a student educational program in its communicable disease hospital. Salary offered begins at \$125 per month with maintenance, and increases of \$5 per month each year until \$135 has been reached. To this basic salary there has been added a cost of living bonus of \$30.64 per month, making the total beginning salary \$155.64 plus maintenance. Apply to Dr. G. F. Burgardt, Deputy Commissioner of Health, Milwaukee, Wis.

Wanted: Public health physicians in Texas. George W. Cox, M.D., State Health Officer, Austin, Tex.

Hawaiian Territorial Board of Health seeks trained engineer to supervise rodent plague control program. Salary range from \$331.67 to \$398.33 per month subject to retirement deductions plus bonus. Position under Territorial civil service system with classification of P-4. For further details address A.P.H.A. Employment Service.

Wanted: Physical therapist by crippled Children's Division. Should be graduate of a school of nursing or of college, with a major in physical education or science; have completed a course in physical therapy; should have had experience in physical therapy, preferably with children. Write for application blank to Merit System Council, 416 Henry Building, 309 S.W. 4th Ave., Portland 4, Oregon.

Psychiatric case worker desired for mental hygiene clinic, Department of Health, Peoria, Ill.

Senior Sanitarian, Alaska Health Department. Minimum requirements 2 years college, 6 months public health course, 2 years' experience. Two additional years' experience acceptable instead of each year college. Monthly salary \$235-\$265. Mary B. Pool, Alaska Merit System, Juneau.

Michigan announces civil service positions now open for orthopedic public

health nurse, Grades II and III classes with the Michigan Crippled Children's Commission. Salary range: Grade II \$230 to \$270 per month; Grade III \$280 to \$340 per month. Grade II not under 23, Grade III not under 25. Must have completed course in orthopedic nursing or physical therapy in approved school. For Grade III position a full-time course of at least 9 months' duration is required. Must have 3 years' experience in public health nursing, one year of which shall have been in supervisory capacity. For Grade III position one additional year of nursing and one additional year of supervisory experience required. Eligibility for certificate in public health nursing and registration as a nurse in Michigan. For further information write Michigan Civil Service Commission, 310 No. Grand Ave., Lansing 4, Mich.

Wanted: Sanitary engineer or chemist to assist in stream pollution survey and later in study of sewage treatment. Should be qualified to perform chemical and bacteriological analyses of water and sewage and chemical analyses of industrial wastes. Nine months employment beginning as near January 1 as possible, with possibility of indefinite continuation, particularly if person is willing to do some other types of analytical work, including coal analysis. Salary \$175-\$250 per month depending on qualifications. Women considered. Address communications to Prof. Gilbert H. Dunstan, Dept. of Sanitary and Public Health Engineering, University of Alabama, Box 1996, University, Ala.

Industrial Hygiene Toxicologist. Calls for person of chemical or chemical engineering background. Position, supervising of chemical work of industrial hygiene service and industrial hygiene laboratory; designing special apparatus for field studies on occupational disease problems; conducting field and laboratory analyses of toxicological exposures in industry; keeping records, interpreting results and preparing records. Requirements, knowledge of chemical laboratory methods and equipment; procedures for qualitative and quantitative analysis of organic and inorganic chemistry; knowledge of chemical methods of determining toxic materials in industry; familiarity with petrographic methods of mineralogical analysis. Immediate temporary appointment will be made, to be followed later by civil service examination to determine permanent status. Salary \$2,900 base, plus \$100 a year war adjustment, or total of \$3,000 per year. Travel expenses also allowed. Must be U. S. citizen. Resident of any state may

apply. Write J. Lynn Mahaffey, M.D., Director of Health, State Department of Health, Trenton 7, N. J.

Wanted: Senior assistant serologists for immediate employment in New Mexico Public Health Laboratory, Albuquerque. Bachelor of Science degree and 1 year experience as serologic assistant in laboratory of recognized standing required. Starting salary \$145 per month. Women or draft exempt men preferred. Address Dept. of Public Health, Box 711, Santa Fe, N. M.

Wanted: Public Health Nurse. Salary \$175 per month and full maintenance, plus \$25 per month for car expense. Must furnish own car. Write Paul D. Crimm, M.D., Director Boehne Tuberculosis Hospital, Evansville 12, Ind.

City of 70,000, southeastern U. S., seeks qualified health commissioner between the ages of 30 and 45, draft exempt. Salary \$4,500 plus auto allowance of \$300 per year. Box V, Employment Service, A.P.H.A.

Assistant Sanitarian in well established Ohio department of health. Minimum experience 2 years required. Merit system prevails. Salary \$1,800-\$2,400. Write Box K, Employment Service, A.P.H.A.

Wanted: Bacteriologist to conduct virus laboratory in the Laboratory Section of the Health Division, City of St. Louis. Applicant must have graduate degree with research and practical ex-

perience in virology. Salary range from \$220 to \$360 a month, depending upon ability. Position under Civil Service. Write Box W, Employment Service, A.P.H.A.

PH1-4, Medical Bureau (Burnice Larson, Director), Palmolive Building, Chicago.

PHYSICIAN distinguished in field of public health medicine is available; B.S., M.S., M.D., D.P.H. degrees, leading schools; enviable career of successful experience in academic and administrative public health work; recognized as able leader. PH1-5, Medical Bureau (Burnice Larson, Director), Palmolive Building, Chicago.

NEWS FROM THE FIELD

HEALTH ADVISORY COUNCIL, U. S. CHAMBER OF COMMERCE

The Chamber of Commerce of the United States has announced the appointment of Dr. Leverett D. Bristol, Executive Director of the Hospital Council of Greater New York, as Chairman of the Chamber's Health Advisory Council and Dr. A. J. Lanza, Chief of the Occupational Hygiene Section of the Office of the Surgeon General, U. S. Army, as Chairman of the Council's Committee on Industrial Health. The Advisory Council, it will be recalled, was created recently to assist the Chamber's Insurance Department in advising business organizations throughout the country on industrial, individual, and community health programs and to cooperate with national, state, and local health agencies.

RECURRENCE OF KERATOCONJUNCTIVITIS IN DETROIT

Dr. Bruce H. Douglas, Health Commissioner of Detroit, announced on January 10 that there is evidence of a recurrence of the highly communicable eye infection, keratoconjunctivitis, first seen in Detroit last winter. During 1943, 252 cases were reported and 21 have been reported so far this year. Dr. Douglas warns eye specialists and industrial physicians who were concerned in holding the disease in check to be on their guard again.

TEXAS STATE HEALTH DEPARTMENT MOVES TO NEW QUARTERS

News has been received of the completion of the new State Health Department building at 400 East 5th Street, Austin, Tex., into which the department has now moved. Dr.

George Washington Cox is State Health Officer.

According to the *Texas Journal of Public Health*, the new center for public health activities in the state has been made possible by federal and state funds. The building incorporates the former state laboratory building as one wing. Construction throughout is reinforced concrete. All health department functions will now be assembled in this building, which is said to be particularly adequate so far as lighting and ventilation are concerned.

DR. GODFREY REAPPOINTED NEW YORK STATE COMMISSIONER OF HEALTH

Late in December, Governor Thomas E. Dewey of New York State announced the completion of his official cabinet with the appointment as Commissioner of Health of Edward S. Godfrey, Jr., M.D., who has served in this capacity by appointment of former Governor Lehman since 1936. Since January 1, 1943, Dr. Godfrey has served in a hold-over capacity.

Dr. Godfrey has served with the New York State Department of Health since 1917. For many years he was epidemiologist and later director of the Division of Communicable Diseases. He subsequently became director of Local Health Administration and then Commissioner. Dr. Godfrey was President of the American Public Health Association 1939-1940.

MICHIGAN OFFERS IN-SERVICE TRAINING COURSE IN MILK SANITATION

An in-service training course for milk sanitarians has been announced by the School of Public Health, University of Michigan, Ann Arbor, for March 6

to 10. According to H. E. Miller, resident lecturer in public health engineering, this course is designed to serve a limited number of key milk control officials in Michigan, Ohio, Indiana, and Illinois. According to Mr. Miller, the purpose of the program is to train individuals as a reservoir from which to obtain teachers for instruction in milk sanitation on the state or local level. Provision has been made for a registration of 60 persons. Beside the staff of the University of Michigan participating in the program, there will be, among others, Professor W. L. Mallmann of Michigan State College; Dr. C. S. Bryan, Michigan State College; Professor I. D. Mayer of Purdue University; Russell Palmer of the Detroit Department of Health; Dr. Warren P. Hall of the Toledo Health Department; John M. Hepler of the Michigan State Health Department; L. F. Warrick of the Wisconsin State Health Department; L. Glen Shields of the Detroit Department of Buildings and Safety Engineering; John Andrews, U. S. Public Health Service, Washington; William J. Guerin, City Health Department, Chicago; and Dr. W. H. Haskell of the U. S. Public Health Service, Chicago.

NEW YORK STATE BEGINS FREE DISTRIBUTION OF TETANUS TOXOID

The New York State Department of Health, Albany, has announced that a limited supply of tetanus toxoid (unprecipitated) which has been prepared and tested by the Division of Laboratories and Research is available for distribution to physicians for active immunization against tetanus. Application for supplies is to be made to the Central Laboratory in Albany. According to the department, the general use of tetanus toxoid is not indicated. However, the active immunization of children and of farm laborers and workers in certain industries who are subject

to repeated injuries may be of definite value. According to the announcement, it is expected that later a combined precipitated diphtheria and tetanus toxoid will be distributed. The preparation is distributed in 10 ml. vials, 3 injections of 1 ml. at 21 day intervals being recommended. A stimulating dose of 1 ml. of tetanus toxoid is recommended at the end of a year and a stimulating dose of toxoid at the time of an injury is said to be considered by the U. S. Army as sufficient to protect against tetanus infection.

PERSONALS

Central States

CHARLES F. ATKINSON, M.D., of Indian River, Mich., has been appointed Medical Director of District No. 1 of the State Health Department, located at Lake City.

L. T. COGGESHALL, M.D.,† who has been Chairman of the Department of Tropical Diseases in the School of Public Health, University of Michigan, Ann Arbor, has resigned to become the Medical Director of a Marine Rehabilitation Unit of the U. S. Navy for patients with tropical diseases and with special concern for the investigation of the problem of relapse in malaria. Dr. Coggeshall will direct a large hospital set-up for this Unit on the West Coast.

GEORGE B. DARLING, DR.P.H.,* President and Comptroller of the W. K. Kellogg Foundation, Battle Creek, Mich., has resigned to become associated with the Division of Medical Science of the National Research Council.

THOMAS S. DAVIES, M.D., has been

* Fellow A.P.H.A.

† Member A.P.H.A.

named Health Commissioner of the Grosse Pointe (Mich.) townships, succeeding BENJAMIN H. WARREN, M.D.,† resigned.

BERTIS C. GWALTNEY, M.D., of Fort Branch, Ind., Health Officer of Gibson County, has been appointed assistant collaborating Epidemiologist of Indiana.

ALBERT F. LITZENBURGER, M.D., of Boyne City, Mich., has been appointed Director of District Health Unit No. 3, with headquarters in Charlevoix and serving Charlevoix, Emmet, Antrim, and Otsego Counties.

RAYMOND J. L. NORFRAY, M.D., of Chicago, Ill., has been appointed Assistant to WILLIAM H. HAINES, M.D., Chicago, Director of the Cook County Behavior Clinic.

ELVIN L. SEDERLIN, M.D.,† former Fargo City Health Officer and lately District Health Officer of Valley City, N. D., has been transferred to Bismarck. This results from the fact that the Valley City District Health Office has been discontinued.

FRED O. TONNEY, M.D.,* formerly Director of Laboratories and Research of the Chicago, Ill., Board of Health—recently Health Director and Research Consultant to the Toledo Scale Company, Toledo, Ohio, under a research grant from the company to the Toledo Health Department—has been named Health Officer of District No. 2, comprising Lake, McHenry, and Boone Counties, with headquarters in Woodstock, Ill.

JAMES WATSON, M.D., Director of the Division of Mental Hygiene, North Carolina State Board of Charities and Public Welfare, Raleigh, has been appointed Chief Medical Officer in the Illinois State Department of Public Welfare, to succeed CONRAD S. SOMMER, M.D., who recently became Deputy Director of the Mental Hygiene Service in the Department of Public Welfare.

Eastern States

JOSEPHINE J. ALBRECHT † has resigned from the staff of the Boston Health League, Boston, Mass., to become Executive Secretary of the Health Division of the Community Welfare Council of Omaha, Neb.

COL. GEORGE BAEHR,* Chief Medical Officer, U. S. Office of Civilian Defense, Washington, D. C., and a member of the Public Health Council of the State of New York, has been elected a member of the board of managers of the State Charities Aid Association, New York, N. Y.

DR. THOMAS D. DUBLIN, M.D., DR.P.H.* has been promoted to become Professor of Preventive Medicine and Community Health in the Long Island College of Medicine faculty, it has been announced by Dr. J. A. Curran, President of the Long Island College of Medicine.

L. WHITTINGTON GORHAM, M.D., of Albany, N. Y., has been reappointed to the New York State Public Health Council for a period of six years by Governor Thomas E. Dewey.

JAMES M. MACINTOSH, M.D., Professor of Public Health at the University of Glasgow, Scotland, and formerly Chief Medical Officer of the Department of Health of Scotland, came to the United States in September as guest of the Commonwealth Fund, New York, N. Y. Dr. Macintosh was the leader in organizing the Provisional National Council for Mental Health in Great Britain and is in this country, according to the *News Letter* of the Commonwealth Fund, to study at first hand small community hospital and rural public health services. He has spoken before many medical and public health groups. He completed his study in December and is returning to Scotland.

* Fellow A.P.H.A.

† Member A.P.H.A.

IDA McROBERTS, R.N.,† has been appointed Public Health Nursing Director in the Cattaraugus County Department of Health, Olean, N. Y., where she has served as Nursing Supervisor. She succeeds MARION I. MURPHY, R.N.,† who has been appointed to the Michigan State Department of Health, Lansing.

J. LOUIS NEFF,* Executive Secretary of the Nassau County Medical Society, Mineola, N. Y., has been appointed Executive Director of the American Society for the Control of Cancer, New York, N. Y., effective January 1.

EDITH H. SMITH, Dean of the School of Nursing, Syracuse University, Syracuse, N. Y., has been appointed Chairman of the Committee on Recruitment of Student Nurses of the National Nursing Council. She succeeds KATHARINE FAVILLE, R.N.,* who has served as Chairman since October, 1941, and under whose guidance recruitment by state and local councils as well as national agencies was inaugurated and has resulted in steadily increasing admissions.

GERTRUDE FOLKS ZIMAND has been appointed General Secretary of the National Child Labor Committee, New York, N. Y., succeeding the late COURTENAY DINWIDDIE.* Mrs. Zimand has been identified with the committee at various times since 1916, and since 1935 has been its Associate General Secretary.

Southern States

JESSE P. CHAPMAN, M.D., of Selma, Ala., has been reappointed Chairman of the Women's Field Army of the American Society for the Control of Cancer.

JAMES E. COLEMAN, M.D., of Fayette-

ville, W. Va., has been appointed by the public Health Council as full-time Health Officer of Fayette County.

WILLIAM B. GRAYSON, M.D.,* of Little Rock, Ark., State Health Officer since 1933, has resigned, effective November 15. THOMAS T. ROSS, M.D., M.P.H.,† of Little Rock, State Director of the Bureau of Local Health Service, has been appointed Acting Head, it was announced.

MABEL M. E. HART, M.D., has resigned as Director of Health for the Tulsa Public School System, Tulsa, Okla., after 12 years' service in the position.

GEORGE JAMES, M.D.,† the Director of the Obion-Lake Health District, Union City, Tenn., has resigned to accept a training position with the New York State Health Department, Albany.

PHILIP G. JOSEPH, M.D., of Oklahoma City, Okla., has been named Director of the Creek County Health Unit, succeeding LELAND F. SHRYOCK, M.D., of Oklahoma City.

ROY H. McDOWELL, M.D., has resigned as Clinic Supervisor of the Durham Health Department, Durham, N. C., to return to private practice.

Food and Nutrition Policy Here and Abroad*

FRANK G. BOUDREAU, M.D.

*Executive Director, Milbank Memorial Fund, New York, N. Y., and
Chairman, Food and Nutrition Board, National Research Council*

FOOD policy is a social and political weapon of no mean importance today. In the period immediately following the first world war very little was heard of it, it was not a subject of public discussion. Not until great food surpluses began to threaten the producers did it become a matter of wide public concern and debate. Yet food policies were adopted around 1925 which became the first links in a chain of events leading to the second world war. For the first guns fired in the war of economic nationalism, which was fought in the period between the two wars, were high tariffs and other economic weapons employed for the protection of agriculture. These measures were not taken in the interests of better nutrition or because greater food consumption was desired or as a means of bringing better food to the poorer

classes. They were taken to improve a given country's trading position and to protect an agriculture whose products could not hold their own against foreign competition. High tariffs and similar trade restrictions provoke retaliation. So a chain of events was begun which led inevitably to more and more bitter economic nationalism. International trade flowed more and more slowly; the life blood of international intercourse grew anemic; agriculture in many countries became a wartime rather than a peacetime agriculture.

Unless drastic action is taken by the United Nations during and after the present war, precisely the same thing may happen again. As the occupied countries are liberated one by one, the pattern of agriculture which they will inevitably adopt will be the old pattern, the prewar pattern. And high tariffs to protect agriculture may again become the first guns fired in a new war of economic nationalism. For if the hungry millions are to be fed, all suitable land must be used for crops for

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

direct human consumption, such as cereals, potatoes, and sugar. In other circumstances the interests of better nutrition would require increased livestock production and rapid restoration of dairy herds. But the immediate task as occupied countries become liberated must be to feed the hungry millions, and this can only be done if all suitable land is planted in crops which may be directly consumed. This policy, if carried far into the post-war years, will again bring surpluses which the world market cannot absorb. It will require the highest statesmanship on the part of the United Nations to call a halt at the proper moment and to persuade governments to transform agriculture with the object of promoting human nutrition rather than of achieving the chimera of national self-sufficiency.

When the bubble of false prosperity was pricked in 1929, governments were forced to recognize the growing problem of hunger among their people. I need not recall to you the signs and symptoms of social unrest in the early 30's which persuaded governments that their only course was to provide work allowances, food, shelter, and clothing to the depressed millions. Hunger and malnutrition side by side with food surpluses which could not be sold was a spectacle which men were not prepared to tolerate. Moreover something of the vast unfolding of new knowledge of human nutrition was being spread throughout the masses, so that public opinion could not brook the idea of malnutrition and misery in the midst of plenty.

Food policies adopted here and in Great Britain during the 30's were alike in some respects but differed widely in others. In both, attempts were made to provide for the distribution of food according to need, but in this country the policy was based upon the existence of food surpluses. We had the food stamp plan whereby foods

in surplus supply were provided to a part of certain low-income groups. Surplus foods and WPA assistance were the basis for an extensive system of school lunches. Surpluses of fluid milk led to various schemes for its distribution free or at low cost. The great danger in our policy was of course the possibility that food surpluses eventually would disappear, which is precisely what has happened. In Great Britain the policy was to strengthen and expand existing social measures without regard to surpluses. For a time the results were very much the same in both countries—a notable improvement in the diets of a large part of the underprivileged—but when war came food surpluses disappeared and with them the basis of our food policy, while in Great Britain war brought decreasing food supplies and increasing need to insure its equitable distribution among the population.

WARTIME ACTIVITIES

In both countries much progress has been made since September, 1939. The food policy in Great Britain has been intelligently conceived along broad lines. It is based on the distribution of food according to physiological need, a guiding principle laid down by the Food Policy Committee and closely followed by the Ministry of Food. Food production in Great Britain has been nearly doubled; milk production has been increased and practically all of it goes into human consumption. Special attention is paid to the vulnerable groups, pregnant and nursing women, infants and children, workers and low-income groups. Less food is consumed by the well-to-do, more by the poor. Best of all, a watchful eye is kept on the people's nutrition by means of dietary surveys and clinical studies so that the onset of danger may be quickly recognized.

Our own food policy has not been

so wise. In the first place the disappearance of food surpluses has destroyed the foundations of our system of food distribution to vulnerable groups, and we have been floundering around to create a new system. Full employment, higher wages, and general wartime prosperity have led many to believe that there are no longer underfed groups in the population. We have no system of dietary surveys and broad clinical studies to enable us to recognize the onset of danger. Socially minded persons in and out of the government believe that many millions have not shared in wartime prosperity and are being squeezed between low fixed incomes and higher prices for food and other necessities.

Our War Food Administration is trying hard to obtain the funds for surveys, but has met with one obstacle after another. It seems to me that health officers and health departments should be particularly anxious to encourage and promote such surveys. If they would write or speak to their representatives in Congress urging the need to provide the necessary funds in the interests of public health, I believe their influence would make itself felt. Moreover, since the states are chiefly responsible for the health of their citizens, and good nutrition is the foundation of health, it would seem that state health and local departments might themselves undertake, by rapid surveys and clinical studies, to ascertain how their vulnerable groups are faring under wartime conditions. I cannot think of any more important task for health departments at this time, and I believe a growing appreciation of their rôle in food and nutrition would do much to increase the public's understanding of their importance.

There are some items which belong on the credit side of our ledger. Fluid milk consumption has been greatly increased because so many more people

can afford to buy it. But this has been accompanied by shortages of milk in some areas, and among some classes. Moreover almost half of our skim milk never gets into human consumption except indirectly through the calf or the pig. Much of the valuable milk solids in the skim milk should be kept for human consumption; this is particularly important at a time when there is a growing scarcity of animal protein, not to speak of the need for supplementing to the utmost the individual's intake of calcium. We have had some success in the feeding of war workers but here as in England much remains to be done in this field. And both here and in Great Britain the nutritional value of bread has been greatly improved; here by the restoration to flour and bread of those important nutrients which have suffered the greatest loss in milling, and in Great Britain by the use of an 85 per cent extraction flour instead of the more usual 72 per cent extraction.

POST-WAR NUTRITION PROBLEMS

Health officers and authorities in nutrition are confronted with immediate and important problems. But the post-war issues transcend all others. Food policy may be important now; it will become vital to world safety after the immediate task of feeding the hungry millions has been accomplished. What can we say about the United Nations' post-war food and nutrition policy? Fortunately some profit has come out of the bitter lessons of the past. The first conference of the United Nations on post-war issues was the conference on food and agriculture at Hot Springs, potentially one of the most important conferences ever held in any country. Without doubt one of the first international institutions to take form during or after the war will be the permanent organization in the field of food and agriculture recommended by the

conference. The food and nutrition policy of the United Nations is set out in the report of the conference; the responsible leaders of at least two of the four great powers have declared that they accept the far-reaching recommendations adopted at Hot Springs. Steps are being taken to draw up the plan and to formulate the constitution of the permanent organization. An Interim Commission, composed of a representative of each of the governments represented at Hot Springs, is dealing with these and other matters. It has recently set up panels of scientific and economic experts to advise it on the form and work of the permanent organization.

The keynote of the conference was that freedom from want means a secure, an adequate, and a suitable supply of food for every man. This goal, the conference declared, can be achieved. Thus nutrition was given its proper place as the guiding principle of food policy in every country. The only method of avoiding a return to the anarchy and economic nationalism of the past, is to make public welfare the sole criterion of food policy.

The Final Act of the conference contains 23 recommendations and resolutions; it includes 26 pages of reports on various aspects of food and agriculture. Every health officer and every nutritionist should obtain a copy and study it seriously, for it is a chart of the future course of the United Nations in food, nutrition, and agricultural policy, and

it provides for the national and international mechanisms which will make possible international collaboration for the welfare of all.

These mechanisms are:

A permanent international organization for food and agriculture, possibly with regional branches.

A national nutrition organization in every country whose business it will be to formulate national food and nutrition policy.

Periodic meetings of representatives of national nutrition organizations under the auspices of the permanent organization.

The obligation of adhering governments to increase the food resources and improve the diets of their people, and to report to one another through the permanent organization on the state of their national nutrition and on the steps being taken for its improvement. Long experience in international coöperation has demonstrated that the obligation of governments to report periodically to one another is one of the best ways of assuring improvement and progress.

In contrast to 1918, when post-war issues and international relations were thought of mainly in political terms, the Hot Springs Conference dealt technically with food, nutrition, and agriculture, subjects of vital interest to ordinary men and women throughout the world. It was clear that at Hot Springs the common man and woman held the center of the stage. The conference painted a picture of how common men and women would profit in diet and health in a post-war world in which nations would work together for the welfare of all. It was a long step forward on the road to sanity in the field of food and nutrition policy.

Vital and Health Statistics in the Federal Government*

SELWYN D. COLLINS, PH.D., F.A.P.H.A.

Division of Public Health Methods, National Institute of Health, Bethesda, Md.

THERE are some 25 federal agencies that routinely handle health statistics including deaths, illnesses, and physical examination findings. In terms of the numbers of records processed, the Division of Vital Statistics of the Bureau of the Census has been the largest of these organizations during peacetime, but with the tremendous increase in the size of the armed forces, the Medical Statistics Division of the Army probably exceeds it, and the Division of Preventive Medicine of the Navy rivals it.

The Division of Vital Statistics handles annually something like $2\frac{1}{2}$ million live births, 75,000 stillbirths, and nearly $1\frac{1}{2}$ million deaths for the country as a whole; it also tabulates about 750,000 marriages in 28 states and 50,000 divorces in 12 states. These data are processed from individual records for each event. In addition the division publishes data on patients in hospitals for the insane and mentally defective which are assembled from reports from institutions.

Because of the large number of detailed tabulations appearing as Special Reports prepared in addition to the Annual Vital Statistics volumes, the work of this division is even larger than the number of records processed would indicate.

The job of the Medical Statistics Division in the Office of the Surgeon General of the Army is the tabulation of various kinds of information about sickness, accidents, and battle casualties in the Army, and physical findings on examination of persons entering the Army.

The Medical Department of the Army assumes responsibility for the health of the soldiers, and provides a complete system of medical and hospital care. Every illness and accident for which the soldier is excused from duty for 24 hours or longer is recorded as an admission to sick report, and facts about it are tabulated, including diagnosis, days sick, and whether fatal or nonfatal. In the peacetime Army, annual admissions to sick report amounted to roughly 700 per 1,000 soldiers; the magnitude of the tabulating job with the present strength of the Army is evident, even when details are omitted from all except a sample of the cases. In the peacetime Army disability per soldier per year amounted to about 11 days, and about 10 of those days were spent in a hospital. The excellence of this medical care may be seen by contrast with the civilian population with roughly 1 day of hospital care per person per year, or about one-eighth of the days of inability to work or pursue other usual activities.

The Army Air Force has a vital statistical setup that is more or less independent of other statistics of the Army; however, the tabulations of

* Presented before the American Association of Registration Executives and the Vital Statistics Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

sickness made by the Medical Statistics Division cover all branches of the Army.

The Navy provides similar medical care to its sailors and marines, with annual admissions to sick report during peacetime of roughly 500 per 1,000 sailors and about 9 days sick per sailor per year. The Navy Department makes the same types of tabulations as the Army. Although the total strength of the Navy is far less than the Army, annual admissions of 500 per 1,000 persons provides a lot of records for tabulation.

The Army and Navy sickness records are unique in that they refer to a definitely known population group. Although selected from the point of view of age, physical status, and conditions under which they are living, the trends of sickness in these groups are of definite interest. For the Army annual sickness rates from all causes and from many specific causes are available for nearly 125 years. Similar records for the Navy are available for long series of years.

Both the Army and Navy maintain in some form a Medical Intelligence Service whose functions are to supply detailed information on health conditions in countries in which the armed forces are likely to operate. The Division of Foreign Relief and Rehabilitation of the State Department collects similar data and also facts about medical and hospital facilities.

The Veterans Administration is already dealing in large numbers of vital records and is due for an increase. In 1942 it gave about a million clinic treatments to about 300,000 individuals, made about 900,000 examinations, and admitted 200,000 persons to hospitals. Unlike the Army and Navy, the Veterans Administration does not have a definitely known population, so is unable to compute illness rates.

Statistics in the Public Health Serv-

ice are not centralized. The weekly, monthly, and annual tabulations of reported cases of notifiable diseases are handled in the Division of Sanitary Reports and Statistics, being received in tabulated form from state and city health departments. The same division publishes reports of quarantinable diseases which are received from foreign countries. The Hospital Division receives and tabulates data on admissions to the 26 Marine hospitals and on treatments in outpatient departments of those hospitals and in other Public Health Service clinics. In 1941 there were about 70,000 admissions with nearly 2 million days of hospital care, and 1½ million clinic treatments of nearly ½ million patients. The most numerous patients are Merchant Seamen, but the Public Health Service also renders medical care to the Coast Guard, to injured federal employees, and to about a dozen other types of beneficiaries. Similar records for the two large hospitals for drug addicts are handled by the Mental Hygiene Division. The statistics of the Venereal Disease Division include special research problems and also data collected in the course of the administration of the coöperative program for the suppression of venereal disease. Two large volumes on serological tests for syphilis among Army selectees have been published.

Statistics in the National Institute of Health are concerned almost entirely with special studies. The major part of the special statistical studies is done in two divisions. The statistical work of the Division of Industrial Hygiene is concerned largely with the health of industrial employees and that of the Division of Public Health Methods with illness and medical care in the general population, and with personnel and facilities available for medical care.

The Children's Bureau of the Labor Department handles a considerable

volume of health statistics, particularly in connection with the administration of laws for the improvement of maternal and infant care, for the aid of crippled children, and for the medical care of wives and infants of men in the armed forces.

The Bureau of Labor Statistics has for many years carried on research in the field of accident classification, accident frequency in representative industries, and time lost on account of industrial accidents. The Bureau of Mines of the Interior Department deals extensively in statistics of mine accidents.

The Employees Compensation Commission administers accident compensation for employees of the federal government, for private employees on navigable waters, and for private employees in the District of Columbia. During the depression this commission also assumed responsibility for injuries of persons on emergency relief work. During 1940 there were some 350,000 injuries reported, but by no means all of them were compensation claims.

In the Social Security Board, the Division of Health and Disability Studies, the Office of the Actuary, and the Bureaus of Public Assistance, Old-Age and Survivors Insurance, and Employment Security all deal in a considerable amount of health statistics. The Division of Health and Disability Studies has concerned itself largely with disability, medical care, and related matters which have or are likely to come up for consideration in connection with the extension of the types of insurance covered by the social security law. The Bureau of Public Assistance collects and analyzes data on the causes of blindness among persons receiving pensions for the blind; it also handles data on chronic diseases and impairments of the parents of children who receive compensation under the dependent children's law. The Bureau of

Employment Security collects and analyzes data on physical impairments and chronic diseases which constitute a special problem in employment placement.

The Office of Education in the Social Security Agency has charge of vocational rehabilitation and is interested in handicapped individuals from that point of view. Its annual reports show the types of impairments and diseases of persons in rehabilitation training during the year.

The Wage and Hour Division of the Department of Labor gets into vital statistics because the law under which it operates authorizes exceptions to permit employment at less than standard rates or hours of persons who are unable to do a full day's work. The consideration of applications for exceptions involves not only chronic diseases and impairments, but also the more severe acute diseases causing only temporary disability in which the person wants to work during convalescence.

The Bureau of Prisons of the Department of Justice has under its charge persons in federal penitentiaries. The medical work in these institutions is done by officers of the Public Health Service supplemented by employees of the Bureau of Prisons. In 1941, in an institutional population of about 18,000, this work included a daily average census of about 1,500 hospital patients with more than $\frac{1}{2}$ million days of hospital care. Some 100,000 medical and dental examinations were given.

The Farm Security Administration tabulates data on admissions to hospitals in connection with insurance plans for rural areas, which it sponsors. In addition, it has conducted physical examinations of a group of rural families to whom relief has been extended, with the idea of finding whether physical condition was a factor in the need of the farmer for relief.

The Tennessee Valley Authority

handles a large volume of both entrance physical examinations and accident statistics among employees on its projects.

The Coördinator of Inter-American Affairs has a Health Division which supports large projects for the protection of the health of workers producing war materials in the various Central and South American countries. Thus considerable data are collected on illnesses treated in clinics and hospitals operating under that organization. Although not a part of the United States Government, the Sanitary Bureau of the Pan American Union also collects and makes available to the American and other governments data on the prevalence of disease in Central and South American countries.

The Procurement and Assignment Service of the War Manpower Commission is charged with procuring physicians and dentists for the armed forces without disrupting civilian medical care. In carrying out these functions, this organization has, in coöperation with the National Institute of Health and the American Medical Association, collected a considerable body of information about the geographic distribution of medical personnel and facilities, the probable future effect upon civilian medical care of the medical recruitment program of the Army and Navy, and similar trends set in motion by the withdrawal of a large proportion of the young doctors from civilian practice.

During its existence, the National Resources Planning Board issued several studies of the health of the nation, usually as chapters in reports on more general subjects.

The agencies thus far discussed deal in some phase of health statistics other than physical examinations. The number of organizations collecting physical examination data is larger than the number handling other types of vital records. At a meeting called in 1941

by the Division of Statistical Standards of the Bureau of the Budget to consider the feasibility of standardizing the methods of coding physical findings, there were 23 representatives from 17 federal organizations which were making physical examinations and were tabulating, or expected to tabulate, the medical findings from them. The fact that so many organizations were represented shows considerable interest in this phase of health statistics.

The tabulation of the findings from the examinations of the millions of men for the Army by Local Boards was undertaken by Selective Service Headquarters. Two reports have thus far been issued on the prevalence of physical defects; the first was based on about 20,000 persons, and the second on 122,000, representing a 10 per cent sample of examinations made in 21 states prior to October, 1941.

The Railroad Retirement Board makes about 15,000 medical examinations per year of persons applying for retirement. Careful consideration is given to each case to assess the extent of the disability of the applicant. A tentative code has been set up for reporting the results of the findings at annual or other intervals.

In 1940, the Civil Service Commission added about 2,200 to its rolls of retired disabled persons. Each was medically examined and found to have some impairment or disease which justified retiring the individual. An unknown number of other persons must have been examined but not retired. The chronic diseases of persons retired for disability are shown in the Annual Report of the Commission, and also the causes of death of about 1,100 persons who died during 1940 out of the 15,000 on the retired rolls at that time.

The National Youth Administration examined in 1941 nearly 150,000 youths 16 to 24 years of age. The findings were analyzed in coöperation with

the National Institute of Health and published in detail. Originally it was the intention to examine all new entrants to N.Y.A. projects, but this aspect of the plan was abandoned even before the organization was abolished.

The Works Projects Administration had detailed plans for the examination of all of its workers to determine their fitness for the specific work to which they were assigned, but the project never got far beyond the planning stage. Some examinations were done in certain areas.

These many government agencies are all interested in vital and health sta-

tistics of the kinds mentioned above. There are no doubt other agencies which I have failed to mention in this brief summary. Some organizations are actively tabulating and publishing the results either as special papers or in annual reports. All are extremely interested in making more use of these various kinds of health statistics collected in connection with the administration of their organizations. Few if any are interested in any form of consolidated statistical organization which would take the data out of the hands of the people who have collected them and are most interested in them.

State Support of Industrial Hygiene Services—An Urgent Necessity*

W. F. DRAPER, M.D., F.A.P.H.A.

Assistant to the Surgeon General, U. S. Public Health Service, Washington, D. C.

THE emergence of industrial hygiene as a major public health responsibility demanded by the war's critical need to save manpower has raised a vital question. Are we making adequate plans to hold the ground that has been gained, and to extend industrial hygiene services on the scale necessary for the successful maintenance of war production? There is much current discussion of post-war planning, which is admittedly essential for making the tremendous readjustment that will come with the war's end, but in industrial hygiene there remains imperative need for concentration on the immediate problems connected with winning the war. There is actually only a skeleton force of industrial hygiene services to meet the increasing demands of continually expanding industrial production. More personnel, more equipment, and better administrative organization are needed for the gigantic task of assisting all war industries on a multitude of health problems affecting production. The admirable improvement of industrial hygiene facilities achieved since the war began can be considered only a beginning of a program which must be further developed in the coming months.

A second question naturally follows—Who should assume the responsibility

for this expansion of service? The answer is indicated by the nature of the job and by present trends. State and local health departments are the agencies which have an inherent responsibility for providing industrial hygiene services as an essential complement to all other activities of the official health program, second to none in importance. The character of this obligation is already indicated by the demands being made of existing services and the size of the task overwhelmingly evident in an appraisal of the dimensions of the growing labor force.

There are an estimated 54,000,000 workers engaged in production in this country, many of whom are women, young people, old persons, and handicapped individuals. Each day thousands of new industrial workers, replacing those called to military service, are being exposed to unaccustomed strains and dangers. New materials and new processes in manufacturing require study and careful control to eliminate hazards. Increased hours of work and higher speed of production expose workers to more risks and to fatigue. As a consequence of these factors and conditions of crowded living in industrial communities, there is increasing disability among industrial workers from both occupational disease and ordinary causes of sickness. However, complete information on the extent of occupational disease morbidity and mortality is lacking because of insufficient industrial health service, and

* Presented at a Joint Session of the Industrial Hygiene and Health Officers Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

inadequate reporting of known cases.

A sizable army of industrial hygiene specialists is needed to cope with all these problems at every level. How far have we advanced in organizing and training personnel to meet this challenge? In answering this question, we immediately note that industrial hygiene has only recently been generally recognized as a field in which state and local health departments should take action. We must all share the blame for this belated acceptance of industrial hygiene as a fundamental public health function, and acknowledge that it has been too long neglected in this country.

The Conference of State and Territorial Health Officers has frequently included discussion of industrial hygiene in its annual meetings, but little action resulted from these deliberations. This association should be credited, however, with maintaining interest in the general problem.

The U. S. Public Health Service admits for its part that it had not been exerting sufficient leadership in stimulating the states to take on industrial hygiene activities prior to 1936. From the time the Office of Industrial Hygiene and Sanitation was established in the Public Health Service in 1914 until that year, the work of the Division had been concentrated on investigations and surveys of industrial health hazards in the field, and in experimental laboratory studies. In 1914 there were only 2 states that had organized divisions of industrial hygiene, and in the interval before 1936, when real expansion began, only 4 more states had added this activity. Then the federal government began to take effective action, realizing that the extension of desirable industrial health practices languished for lack of promotion on the part of the federal and state governments. The Social Security Act of 1935 made possible, among other benefits, the setting up of a definite plan for establishment of in-

dustrial hygiene divisions in the states. In 1936 10 states added this function to their health department program with the aid of federal grants-in-aid. Each succeeding year since then more states have developed industrial hygiene divisions until there are now 38 states carrying on such activity.

Expansion within the states is now going on in equally vigorous fashion. Four states have already established local divisions in city and county health departments, and one other large state maintains district laboratories. The Division of Industrial Hygiene, National Institute of Health; in the Public Health Service has helped in each step of this development by providing advisory service on both technical and administrative problems. Surveys of all industrial health hazards in certain states have been made to provide evidence on which requests for appropriations could be based in setting up new state services.

The responsibilities which the state units are assuming cover a far wider field than was originally conceived. When industrial hygiene personnel visit an industry today they are presented with all kinds of problems for solution, and in turn are prepared for more varied requests than formerly when investigation of a specific occupational hazard was the only service expected on a plant visit. Today the representative of the Industrial Hygiene Division may be confronted with questions on sanitation, nutrition, communicable diseases, medical care of injuries, nursing duties, safety and health education, and a variety of related problems in addition to health hazards of work processes.

From the health department point of view, the changes in public health practice in other special fields, and the general recognition of the expanding function of health departments have been influencing the scope of industrial hygiene activities. Health administrators

are now more aware of their responsibility to extend health services to all people of their communities, and to find new ways of carrying these services to the groups who most need them. The factory is found to be a strategic place in which a large proportion of adults can be provided health services, in the same manner that the school has long served as a center for child health programs.

The much publicized facts of industrial absenteeism point out the health department's responsibility to industrial workers. It is neither accidents nor occupational diseases which cause the greatest amount of lost time from work, but the everyday causes of illness common to adults. Most state and local departments have already established services to deal with many of these problems of adult health, including tuberculosis, venereal disease, cancer, dental hygiene, mental hygiene, maternal health, and nutrition. At the same time that the health department attempts to extend these services to workers, industry is seeking the various services which health departments have to offer. It is logical that industrial employers will turn to the division of industrial hygiene for assistance in securing health department services, having first hand acquaintance with this branch of the department. It follows that the division of industrial hygiene can well act as a liaison for the other divisions of the state health department and make initial contacts with industries in arranging to have the desired services brought to industrial workers.

In addition to this coördinating function within the health department, the state division of industrial hygiene has equally important responsibilities in maintaining working relationships with other state agencies and organizations. Chief among these agencies are the state department of labor, and the industrial accident commission. Factory

inspectors employed by the departments of labor to check safety measures have in some instances received training for detection of occupational disease hazards through coöperative arrangement with the divisions of industrial hygiene. Industrial accident commissions can furnish the industrial hygiene service with information on occupational diseases reported to that agency as required by law. For example, such a working arrangement is in effect in California, where the division of industrial hygiene in the health department makes investigations of the cases reported to the commission. In this state factory inspection is a responsibility of the commission. The inspectors call upon the industrial hygiene service to make technical investigations of potential health hazards which they have found in the industry. The results of these surveys are reported to the commission, since that agency is legally responsible for enforcing rules and regulations concerning protection of the health of workers. Similar relationships have been developed in Wisconsin.

In most states there is a belief that the state health department should operate in this field only on an educational plane, using its findings to persuade management that changes for correction of hazards are necessary. Education is the first approach, as in other health department activities, but the authority which may be needed in certain cases is not lacking, since every health department has sufficient power in its basic laws to take action for the prevention of occupational and other diseases.

Another function of the state health departments related to the investigation of factory conditions and securing control of hazardous conditions is the reporting of occupational diseases. In some states the law requires reporting of these diseases, usually to the health

department. However, comparatively small numbers of cases are reported in most states, which suggests that the state health department has an obligation to carry on an educational program on this specific problem. Physicians must be better informed on the nature and evidences of occupational diseases, particularly those likely to occur in the industries of their respective communities. They must acquire the same concern to report occupational disease as they generally have for reporting of communicable diseases.

Still another responsibility of state public health administrators is the establishment of adequate rules and regulations aimed at preventing occupational diseases through control of hazards. In a few states the health department is especially charged with this responsibility, in others the state agency so designated rightfully expects technical assistance from the health department. For example, the Maryland Compensation Law explicitly ascribes the duty of formulating, adopting, and administering rules and regulations designed to prevent and control occupational disease to the State Health Department and to the Baltimore City Health Department.

Similar coördinate functions of state agencies in the matter of dealing with investigation of cases of compensation claims is needed. North Carolina furnishes an example of this type of coöperation. The occupational disease law of the state provides that the Industrial Commission shall adjudicate the law and shall make investigations of health hazards in certain industries where a silicosis and asbestosis hazard exists. The commission has designated the State Board of Health as its agent and all investigations and physical examinations are conducted either by the State Board of Health or under its supervision. Public health administrators in other states should be prepared

to render such services whenever called upon to do so, unless specific legislation prohibits the use in litigation of the results of investigations.

It is sometimes claimed that industrial hygiene should be administered under the direction of those agencies concerned with enforcing labor legislation such as factory inspection, wages and hours of labor, and workmen's compensation. The rôle which a health department should play in connection with compensation cases should be that of an impartial investigator of industrial health hazards. Placing such a function in the hands of the compensation agency would do away with the wholly impartial activities which we feel should be preserved.

In every state there are various non-official agencies and groups interested in promoting particular phases of industrial health with whom the state health department needs to develop effective working relationships. Among these is the state medical society, which has followed the leadership of the Council on Industrial Health of the American Medical Association in setting up a state committee for industrial health. Local medical societies are likewise being urged to develop such committees for the purpose of stimulating physicians to take active part in meeting local industrial health needs.

The state manufacturers associations are becoming more sensitive to the problems of industrial hygiene and may generally be counted on to give support to the program of the state health department. In the same manner, chambers of commerce are taking active interest under the guidance of their national Committee on Industrial Health.

Labor unions are coming to appreciate their own vital stake in the extension of industrial health services, and are making their wants and needs felt. Frequently state divisions of in-

dustrial hygiene receive requests from unions for help in investigating hazardous or unhealthful working conditions affecting their members, and for information concerning these hazards. Health departments can evolve plans for working with the labor-management health committees established in industries under the sponsorship of the War Production Board. These committees are found to be useful intermediaries for promoting all types of industrial hygiene and general health activities within the plant. They should be provided with suggestions for carrying on continuous programs.

Professional training and refresher courses are another field of responsibility for directors of divisions of industrial hygiene. Short institutes are needed for physicians, engineers, and nurses already engaged in industries to bring them up-to-date on handling the newer problems, and on the latest techniques. New personnel require complete courses covering the fundamentals of their work and the relationships of the health program to the other functions of industrial management. Such courses can be developed in cooperation with universities, medical societies, industrial nursing associations and engineering societies, as many state and local industrial hygiene divisions have already shown.

Coöperation should also be given to the state departments of education for development of instruction on industrial hygiene in vocational school training courses, and in the local program of Engineering, Science, Management War Training Courses sponsored by the U. S. Office of Education.

These are only brief suggestions of the major responsibilities of a state division of industrial hygiene, but they should suffice to indicate the broadened conception of the functions of such a division. Further arguments are not needed to show that substantial support

must be provided for such an important service if it is to maintain the confidence of industry and all the agencies now looking to it for assistance.

Total appropriations for these state and local units for the fiscal year 1943-1944 have now reached the sum of \$1,222,295. Forty-nine and eight-tenths per cent of this total is derived from federal grants-in-aid, a slightly smaller percentage than that of the past year, since a number of states have increased the state's appropriation for this year.

When we consider the varying amounts of self-support given by the individual states to maintain their divisions of industrial hygiene, it is found that 6 states and 1 county are securing all their funds from federal grants. Seven states and 1 city depend upon federal funds for over 75 per cent of their budget for industrial hygiene. Twelve states and 1 city are aided to the extent of 50 to 75 per cent. Seven states are receiving 25 to 50 per cent, and 4 states require less than 25 per cent of federal funds. Finally, there are 4 states and 4 city divisions which receive no federal assistance, maintaining their programs entirely on their own appropriations.

During this emergency, the states are receiving much additional assistance beside federal grants in the form of loan of personnel from the Public Health Service.

Approximately 60 persons, including physicians, engineers, chemists, a dentist, and 3 nurses, are now loaned to 27 states. In several of these states these workers constitute either the entire staff or a major part of the state division. Special war appropriations made under the Emergency Health and Sanitation Act have provided for the establishment of this plan to loan both personnel and equipment to states. At the present time, states are requesting more personnel than are available, since

there has been a limiting of the number that can be added to the Public Health Service staff.

A number of states are successfully finding the only possible solution to the problem, i.e., to secure adequate state appropriations to maintain at least the minimum essential personnel to carry on their industrial hygiene programs. The obligation of the states clearly lies in this direction, since the loan of personnel by the U. S. Public Health Service can be expected to terminate with the end of the war. State health department administrators should be planning not only to replace their borrowed workers, but to augment their present staff with sufficient numbers of the various professional personnel needed to conduct an adequate and balanced program. Only 14 of the 38 state divisions have staffs consisting of more than 4 professional employees.

The total number of state personnel provided for in the budgets of state and local industrial hygiene units for the fiscal year 1943-1944, is 354. Of this total, 46 are physicians, 141 are engineers, 45 are chemists and other technical workers, 22 are nurses, 1 a dentist, and the remainder—100, are clerical workers.

Each state division should have on its staff as the minimum essential personnel to conduct industrial health surveys, a physician, an engineer, a chemist, and a nurse, supplemented by a clerical staff to assist in making reports and keeping records. Large units will require a number of each of these types of personnel. A new development is provision of advisory service in the special field of industrial dentistry. Three states have pioneered in this direction by employing a dentist to promote dental services in industry as a part of the industrial hygiene program. Already health education programs in industry require the addition of a health educator to state health depart-

ment staffs for full-time assistance on industrial health education.

The essentiality of these industrial hygiene services cannot well be questioned by state legislators if the case be properly presented to them. Persuasive facts and dramatic evidence of accomplishments and needs should be brought before them now while public support can be counted on.

If action is not soon taken we may witness a demobilization of some of the state industrial hygiene units when the retrenchment of federal support takes place at the end of the war.

The type of program needed has been well demonstrated by the U. S. Public Health Service and a number of well organized state and local divisions of industrial hygiene. The Public Health Service stands ready to give continuing help to states in preparation of information for requesting state appropriations. In a recent instance, for example, a representative of our Division of Industrial Hygiene accompanied the state health commissioner of a western state on a visit to the governor, and succeeded in obtaining \$20,000 from emergency funds for urgent needs of the state's division of industrial hygiene.

The appeal for state appropriations can be presented as an immediate emergency need, and at the same time postulate a permanent program to meet peacetime requirements. If need be, these requests can be met by some adjustment of the total state health department budget, curtailing some less essential activity. Too often budgets and programs once established are continued each year because inertia prevents the making of an objective appraisal of the relative merits of various programs. Now is the time for critical review of state and local health department activities, while other revolutionary changes are making adjustments easier to propose.

To make an adequate estimate of a

state's needs in industrial hygiene services, the health administrator may first have to acquire a deeper understanding of the subject, particularly if he has not had training in the field, or familiarized himself with recent developments. There may be a tendency for health officials to regard industrial hygiene as an especially technical field in which they may honestly admit having no more than a speaking acquaintance. One aid for dispelling such feelings is the *Manual of Industrial Hygiene* recently prepared by the Division of Industrial Hygiene, National Institute of Health.

The workers who receive the ultimate benefits of an industrial hygiene service deserve our best effort and con-

sideration. They are giving their best to produce war materials which are saving us all, and the nation is thankful for their magnificent accomplishment. These home front battalions should be assured that there will be no let down of the protective program securing their own lives and health as they continue to give our fighting men the weapons for victory.

The industrial workers of our country have a right to this confidence in their health departments. For the future, they should have hope of greatly improved health safeguards in their working places as a part of the promise of a better world for all. Now is the time for laying foundations to secure these hopes.

A Severe Epidemic of Meningococcus Meningitis in Chile, 1941-1942*

MARIO PIZZI, M.D.

Director, Division of Communicable Diseases, Province of Santiago, Chile

A SEVERE epidemic of meningococcus meningitis occurred in Chile in 1941-1942 (Chart 1). From June, 1941, until December 31, 1942, there were reported 5,885 cases with 928 deaths (a case fatality rate of 15.9 per cent).

As far as we know, Chile, which has a population slightly over 5,000,000, had never previously suffered an epidemic of meningococcus meningitis, except for a small outbreak of 10 cases in 1938 in a navy training school on an island. In the preceding years, only a few cases were reported annually; a total of 53 cases from 1932 to 1940, inclusive. Our population, therefore, apparently had little immunity against the disease and this fact might explain the very high incidence in this epidemic. Furthermore, the poorer classes of the population live in very crowded conditions and a survey made some time ago in the slum sections of Santiago showed an index of 7 persons per room, and an index of 2.9 persons per bed. The nutritional status of these people is rather poor, and even the weather was against us, since the winter of 1942 was particularly cold, compared with our usual climatic conditions. So we had all the requirements for the epidemic spread of a disease transmitted via the respiratory tract—lack of natural immunity,

overcrowding, and conditions that would decrease individual resistance, such as poor nutrition and becoming chilled.

The epidemic began in Valparaíso, our main port. The first cases were reported from a welfare institution for children, in June, 1941, spreading rapidly through the city and then over the whole province of Valparaíso. This province has a population of 433,233 people, according to the 1940 census. The attack rate per 100,000 population in this province was 89.2 for 1941, and 188.1 for 1942.

In Santiago the first case was reported on August 25, 1941, in a young soldier. Another case occurred in another soldier within 3 days. These two men belonged to an engineers' army school. In the days immediately preceding their illness they had been working very hard in connection with some floods which occurred near the capital, and had been subjected to prolonged exposure in cold water and to strenuous physical work. The third case was in a daughter of one of the contacts of the soldiers, and the fourth case was in an army physician, who had not had actual contact with the patients, but who worked very closely with a physician who took care of the soldiers.

Knowing the particularly favorable conditions for the spread of an epidemic, we were very worried, but at that time the incidence in Santiago did not become particularly alarming. The

			Total	13.6	101.3

attack rate per 100,000 population that year for the whole province was 23, a figure by far below that for Valparaiso (89.2). However, in the winter of 1942 the epidemic took an explosive form in Santiago, and the incidence for that year was 261.6 per 100,000. The epidemic, which in 1941 was localized in our two main cities, Santiago and Valparaiso, spread in 1942 all over the

country, mainly in the northern and central zones and relatively sparing the southern one, as can be seen in Table 1, in which the provinces are shown in order from north to south.

AGE DISTRIBUTION

In Table 2 the age-specific morbidity and mortality rates are presented. As was to be expected, the

younger age groups suffered higher morbidity and mortality rates.

HOUSEHOLD SECONDARY ATTACK RATES

In order to study the secondary attack rates among the contacts of cases, 9,668 individuals living in the same households of actual cases were studied, according to age and the degree of overcrowding. The data are given in Table 3, from which we can make three statements: (1) 2.5 per cent of the contacts acquired the disease; (2) the secondary attack rate was higher among those under 15 years of age; and, (3) there was a statistically significant difference

between the rate among those living under slight conditions of overcrowding and the rate for those living under conditions of severe overcrowding.

CARRIERS

No meningococcus carrier survey had been made of the population prior to the epidemic. During the outbreak, carrier surveys were made of various groups. A total of 12,870 individuals were cultured, among whom 429 carriers were found, giving a rate of 3.25 per cent. The rate varied from 1 per cent among the beggars in the "flop houses" (in the open all day), to 55 per cent

TABLE 3

among the 18 men in the barracks with the 2 soldiers forming the first 2 cases.

An attempt was made to study the action of the sulfa drugs in eliminating the carrier state but, unfortunately, we had to suspend our study due to shortage of sulfa drugs. Our figures are too small to form a basis for conclusions.

TYPES OF MENINGOCOCCI

During the 4 years preceding the epidemic only 12 strains of meningococci had been recovered. Six belonged to Group III, 4 were Group I, and 2 agglutinated both Groups I and II. No Group II or IV meningococci were found:

During the early part of the epidemic, 116 strains of meningococci isolated from carriers and 53 strains from spinal fluid were typed. Among the strains isolated from carriers, Group I was more frequent than Group III (26.7 per cent compared with 3.4 per cent). Of the strains, 69.8 per cent could not be typed. Groups II and IV were not found.

Among the strains isolated from spinal fluids, on the contrary, Group III markedly exceeded Group I: 75.7 per cent compared with 9 per cent in Santiago; 70 per cent compared with 30 per cent in Valparaiso. The percentage of strains which could not be typed was low (9 per cent in Santiago and none in Valparaiso). Three strains were found in Santiago that agglutinated both Groups I and III, and were classified as intermediate strains. In neither city was Group II or Group IV found.

Without giving the technic of isolation and typing in detail, suffice it to say the swabs were streaked on the blood agar plates within 3 hours after they had been taken. Non-pigmented strains fermenting glucose and maltose were tested with the specific sera prepared with the standard strains of Sarah Branham.

The above figures as to groups are probably too small to be conclusive.

The study has been continued but the results are not available as yet.

ADMINISTRATIVE PROBLEMS

Having given some of the epidemiological and bacteriological aspects of the epidemic, I would like to present now in some detail the administrative problems associated with the control of the epidemic in Santiago.

As stated before, in 1941 the epidemic was not very alarming for a province the size of Santiago (1,261,717 population). The maximum number of cases reported weekly was 24. During the first 6 months of 1942 the situation improved in that only 325 cases were reported, the weekly incidence being as low as 2 cases during the 12th week, and as high as 34 in the 26th week. However, during the first days of July (our winter), coinciding with a very low temperature for our usual climatic conditions, the epidemic took on an explosive form.

Of the 3,602 cases reported in 1942 in Santiago, 3,277, or 91 per cent, occurred during the second half of the year. In a few days we passed from an average of 22 cases per week during the preceding 2 months to 25, 40, 60, and even 75 cases *a day* at the peak of the epidemic. The public was seized with panic. As an example of the terrifying manner in which the disease struck some households, in one family of 9 persons there occurred 4 cases within 72 hours. Two of these patients died within 48 hours of onset. Three to 4 per cent of the cases among young children died in a few hours with the Friedericksen-Waterhouse syndrome in spite of intensive treatment. In some of these cases the microorganisms were so numerous that in a blood smear the red blood cells could hardly be seen for the meningococci. The Public Health Service's free communicable disease diagnostic service became swamped; it was impossible for the

diagnosticians to cover the 80 to 100 calls received each day.

At this point, Dr. Eugenio Suarez, the General Director of Public Health, requested and immediately obtained the extraordinary powers that in case of emergency are given to him by the *Sanitary Code*. Since in an epidemic of meningococcus meningitis there are not at the present time effective measures to prevent its spread, our efforts were primarily devoted to supplying prompt and adequate medical care to the patients in order to decrease the case fatality rate. Our campaign, therefore, was planned on this basis and no efforts were spared in an attempt to reach the patients in the shortest time possible. For this purpose we evacuated within 24 hours a 400 bed hospital to receive patients 5 years of age and over. For the children under 5, 100 beds were available in a children's hospital, and 60 beds were held in reserve in other hospitals. The director of the campaign moved his headquarters to the hospital and all the personnel were under his direct command. A 24 hour diagnostic service was available, staffed by 25 physicians, divided into five shifts, who worked 3 hours each day and one night of every five. Each shift included one pediatrician. This diagnostic service was available not only as a consultation service to private practitioners, but was available as well directly to the public.

This personnel was selected from the interns of the wards where the cases during the preceding year had been hospitalized. Having seen several hundred cases, these interns were very familiar with the different manifestations of meningococcus infection. Notices on the front page of all the newspapers instructed the population as to the chief symptoms of the disease, the way in which they could get the physicians' service, and that this service was absolutely free. Each physician had avail-

able at all times a car from the Public Health Service in which there was a special bag containing sulfa drugs in tablets and in solution, syringes and needles already sterilized, and cardiovascular drugs to treat the cases in collapse. They were instructed to begin the treatment at the bedside of the patient upon the slightest suspicion of meningitis. A record stating the hour at which the sulfa drug was given as well as the dose was left in the home and brought with the patient when the ambulance was sent for him.

At the admission room in the hospital the patients were carefully checked, and if the diagnosis was not clear they were sent to an observation ward where they were periodically reexamined and sent either to the wards or to another hospital if a diagnosis other than meningitis was reached. If the physician upon his first visit to a household considered that the case could be kept under observation at his home, he reported to the hospital the hour at which a second visit should be made and his instructions were carried out by the shift that happened to be on duty at that time. For the private practitioners a 24 hour consultant service was available, and in some instances the same patient was seen 3 or 4 times within 24 hours until a final diagnosis was reached. It was expected that a visit would be made within 2 hours of each call, and for this purpose the telephone operator had a book in which the time of the call and the time at which the patient was seen were recorded, as well as the diagnosis which was made. In this way it was easy to control the efficiency of the service. Inquiries were made as to the reasons for delay, and improvements were effected if deficiencies were found. The physicians while attending the calls were in constant communication with the hospital to save time if there happened to be a new call in their neighborhood.

One night a man called the hospital saying that his son had suddenly awakened with vomiting and was complaining of severe headache. The home was seven miles from the hospital but it happened that 5 minutes later one of our physicians telephoned in and he was only 2 blocks from the patient's home. The father was astonished when he saw his call attended less than 10 minutes after he had requested our services. The case proved to be meningitis and the treatment was immediately started, 10 minutes after the known onset of the disease. Obviously this was an unique exception, but the great majority of the calls were made within the 2 hour objective. This practice of working at high speed contributed to reassure the population and to terminate the "epidemic neurosis" which had developed. Although fear was useful at the beginning of the campaign to make the public aware of the existence of the epidemic, it became a heavy burden to the medical personnel since many calls were only due to panic. Some people requested our services for merely a slight headache. The reassurement of the population was shown by the rapid decrease in the ratio of requests for services to the number of actual cases found.

Power to use the police in enforcing his resolutions was given to the director of the campaign, a weapon that can be very useful if wisely used. To show under what conditions we had to work and how compulsion sometimes is necessary to save a life, I like to relate the following experience.

One day, late in the evening, we received a telephone call from the director of an outpatient clinic belonging to one of our social security agencies, saying that a diagnosis of meningitis had been made in a baby girl 6 months old. When the mother was told that her baby was severely sick and had to be sent to a hospital at once, she refused, saying, with the fatalism that characterizes some of the lower segments of our population, that

since the baby was going to die, she preferred to have her die at home. Believing that a baby's life should not depend upon the ignorance of her mother, the director of the clinic ordered a policeman to hold the woman until the ambulance came. Unfortunately, a social worker not knowing what had occurred and seeing that the mother was hysterical told the policeman to release the woman and that she would take care of the case. Upon receiving the call we went immediately to the address, in a very poor, slum area, and found nobody home. We came back that night and found from 8 to 10 people in the house, some of them drunk, but no trace of the mother or the baby. We explained to them that we were looking for the baby, trying to save her life, but they stated they did not know where the baby was. After all arguments for obtaining the new address were exhausted, we thought that we were justified in using force, and secured four policemen from the police station. Again, we tried to get the information voluntarily but upon their refusal, we told them that everybody was going to be taken to the police station and stay there as long as necessary to make the baby appear. With this threat and in view of the fact that it was a cold, rainy, winter night, they thought that it was better to give the information than to leave the house. We found the baby at 1 o'clock in the morning, 14 blocks from the original address, in a bed with her parents and 2 brothers, 2 and 4 years old, in a small room where there were 4 other people as well. The baby was immediately carried to the hospital and, fortunately, she recovered.

In the rural areas near Santiago we encouraged all the local physicians to send even suspicious cases to our hospital. Ambulances were available at strategic points and we covered the areas where, due to the low density of the population, there was no medical service readily available. One day we received a call from a rural police station in the Andes 50 miles from the capital, informing us that a man had been found unconscious in the mountains. An ambulance with a physician was sent immediately. The patient was found to be suffering from a fulminating case of the disease, and he received intravenous treatment at the police station, with ultimate recovery.

The reporting of cases by private physicians was poor. This fact was readily shown by our spot map which indicated an extremely high number of deaths in relation to the number of cases in the better residential areas of the city. This high death rate was fallacious since the wealthy people have better medical care, and could only be explained by poor reporting of cases. At our request the reporting improved slightly but still was poor. So, overnight we "froze" the sulfa drugs. The drug stores could not sell a single tablet unless the name, address and diagnosis of the patient were stated by the physician in the prescription. Furthermore, in order to save sulfadiazine for the meningitis cases, this drug could only be sold for the treatment of that disease. In case a physician needed sulfadiazine for the treatment of other conditions he had to ask permission of one of the members of a commission of 4 physicians who were available day and night: two from the Public Health Service, one representative of the medical society, and one from the surgical society. Each morning the drug stores sent a list to the offices of the Public Health Service with the names and addresses of the patients to whom sulfa drugs had been sold in the preceding 24 hours. All these patients were checked by physicians of the Public Health Service within the day, and if the conditions for proper care and isolation were satisfactory they were allowed to stay at home; if not, they had to be hospitalized. Fortunately, always after contacting the attending physician the conditions either were improved or the family accepted our suggestion as to hospitalization.

Besides the prompt and effective medical care, routine measures of control were taken. The beds in army barracks and schools were separated more than 1.4 meters, public gatherings

were discouraged, the capacity of the theaters was decreased to a certain percentage of the number of seats according to the facilities for ventilation, and an adequate publicity and education campaign was conducted through radio, newspapers, and leaflets. The patients at the hospital could only be visited under special circumstances determined by the director of the campaign. Twice a day, bulletins stating the condition of the patients were issued at the hospital and at the offices of the Public Health Service downtown.

There were received at the hospital 1,658 patients from July 1 to December 31, 1942. Of these, 1,608 were meningococcus meningitis, 29 tuberculous meningitis, and 21 were suffering from other diseases and transferred to other hospitals as soon as the diagnosis was made. Of the 1,608 meningitis patients 117 died, giving a case fatality rate of 7.27 per cent which is far below the average case fatality rate for the patients who were treated elsewhere (18.9 per cent). This low case fatality rate may be due in part to the fact the case fatality rate in children under 5 years of age is particularly high and such children were treated in other hospitals, but no doubt partially to the early treatment obtained through our service, in comparison with those treated at home.

Some evidence of the effects of our campaign are possibly indicated in a comparison of case fatality rates before the campaign started and after its inception. During the second half of 1941 the case fatality rate was 23.1 per cent. During the first half of 1942 it was 22.3 per cent, while during the second half of the year when the campaign was in effect it was 14.5 per cent. This drop in the case fatality rate is statistically significant. The figures from which they were calculated include all age groups, and the treatment was the same in the 3 periods. There are

other factors, of course, which might have played a rôle in the decrease in the case fatality rate in the third period, such as better diagnosis and more complete reporting, but it is felt that it is also a reflection of the medical care program which was instituted.

In order to make a study of the case fatality rate according to the place of treatment, 1,872 records for the 3,602 patients or 51.66 per cent, were taken at random. This sample, as was expected, proved to be representative, as determined by a comparison of the age and sex distribution in the two groups. Of the 1,872 patients, 1,736 were treated in a hospital and 136 at home. The case fatality rate among the former was 12.5 per cent while among the latter it was 31.6 per cent, showing again the influence of hospitalization upon the prognosis.

An attempt was made to study the influence of the time elapsed between onset and hospitalization, and according to the duration of the disease. Sixteen hundred and sixty-seven cases were studied from this standpoint; 65.7 per cent were hospitalized within 48 hours of the onset of the disease. Of these, 45.1 per cent left the hospital before the 12th day, discharge being on the basis of clinical recovery. Among those hospitalized after 48 hours from onset a somewhat smaller percentage was discharged within 12 days, 40.4 per cent. This difference,

however, is statistically significant. The case fatality rate among the two groups was practically the same, probably because the fulminating, rapidly fatal cases fell into the group receiving early care, thus counteracting the low case fatality rate established by the other cases in this group.

We will never know the actual extent of infection which occurred. All gradations were experienced from apparently completely passive carriers to the typical, textbook cases of meningococcus meningitis, which, of course, represent only a fraction of the total number of clinical conditions due to the meningococcus infection. Sore throats were not infrequently associated with almost pure cultures of meningococci. Arthritis with effusion in the joint was found to be due to the meningococcus, and many bizarre clinical conditions were encountered which I shall not take time to discuss in this paper.

In conclusion let me state that this should be considered a preliminary report since the outbreak has continued in 1943 and data are still being collected. However, the incidence this year apparently will be lower than in 1942. I have merely tried to inform you of some of our experiences in this overwhelming epidemic of meningococcus meningitis. I hope you will never have such an epidemic, but if by misfortune you do, I hope our experience may be of some help to you.

Post-War Implications of Fluorine and Dental Health*

The Use of Topically Applied Fluorine

JOHN W. KNUTSON, D.D.S., DR.P.H., AND
WALLACE D. ARMSTRONG, M.D., PH.D.

*Dental Surgeon, Division of Public Health Methods, National Institute of Health,
U. S. Public Health Service, Bethesda, Md.; Professor of Physiological
Chemistry, Laboratory of Dental Research and Division of
Physiological Chemistry, University of Minnesota,
Minneapolis, Minn.*

PRESENT knowledge and trends of evidence on the relationship of fluorine and dental health indicate that the incidence of dental caries can be reduced by either of two methods of fluorine therapy. These methods are: (1) the addition of 1 part per million of fluorine to municipal water supplies; and (2) the topical application of fluoride solution to the teeth. It is the purpose of this paper to present experience with and to discuss the relative usefulness of the second method of fluorine therapy.

The first published reports on the use of topical application of fluoride solution to the teeth of humans were made in 1942 by two independent investigators. Bibby¹ reported on the application of 0.1 per cent sodium fluoride solution to the permanent teeth of 89 children aged 10 to 13 years, and Cheyne² reported on the application of 0.05 per cent potassium fluoride solution to the deciduous teeth of 27 children aged 4.5 to 6 years. Both of these investigators concluded that the treatment effected a 50 per cent reduction

in the incidence of dental caries. In a subsequent report on the second year of observations on the caries experience in his study group, Bibby³ concluded that the effectiveness of the treatment had decreased slightly.

The most recent report on experience with topically applied fluoride was made by Knutson and Armstrong,⁴ who obtained a 40 per cent reduction in the yearly incidence of dental caries by using a 2 per cent solution of sodium fluoride. A condensed analysis of the major findings of this study of 289 treated children and 326 negative control children, aged 7 to 15 years, will be given below.

During an 8 week treatment period, the 289 children in the treated group received from 7 to 15 applications of the fluoride solution to the teeth in the upper left and the lower left quadrants of the mouth. The teeth in the right quadrants were not treated and were utilized as direct controls. The incidence of new caries in the treated and in the untreated permanent teeth during the first year after treatment are compared by mouth quadrants in Table 1. Because of the bilaterally equal occurrence of dental caries in population groups, it is expected that the

* Presented before the Oral Health Group of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

TABLE 1

The Incidence of Caries in Permanent Teeth Previously Free of Caries; Comparison of Fluoride-treated and Untreated Quadrants in Each Jaw of 289 Treated Children

Item	Upper Jaw Persons	Lower Jaw Persons
Lower incidence in treated quadrant	63	48
Higher incidence in treated quadrant	26	30
Incidence equal (one or more) in treated and untreated quadrants	15	12
No new carious teeth in either treated or untreated quadrants	185	199
Total number of children	289	289

number of instances in which individuals have more caries in the left than in the right quadrants of the jaw will equal the number of instances in which the opposite result is obtained. It will be noted from the data in Table 1 that for the upper quadrants, 26 children had more, whereas 63, or 2.4 times as many children, had fewer new carious teeth in the treated than in the untreated quadrants. For the lower jaw, 30 children had more, and 48, or 1.6 times as many children, had fewer new carious teeth in the treated than in the untreated quadrants.

The number of permanent teeth that were non-carious at the time of treatment and the number of these that became carious during the following year are presented for the treated group of children in Table 2. In addition, the numbers of new carious tooth surfaces which occurred in the non-carious and in the previously carious teeth are also given. According to the data in this table, 54 non-carious teeth in the upper

left and 100 in the upper right quadrant were attacked by caries; a difference of 46.0 per cent less new caries in the treated than in the untreated upper teeth. In the lower jaw, 46 new carious teeth occurred in the left and 66 in the right quadrants; a difference of 30.3 per cent less caries in the treated than in the untreated lower teeth. These findings, together with those presented in Table 1, indicate that the treatment was more effective for the upper than for the lower teeth.

As would be expected, the number of tooth surfaces attacked by caries is highly correlated with the number of teeth attacked. However, it is important to note (Table 2) that, although the numbers of tooth surfaces which became carious in previously carious teeth are lower in the treated than in the untreated teeth—49 in the treated and 57 in the untreated upper teeth, and 64 in the treated and 72 in the untreated lower teeth—the differences are relatively insignificant. Ap-

Untreated (right)	1,246	66	75	72	147

DF = Carious (decayed or filled)

parently the treatment is of questionable value in preventing caries attack on the non-carious surfaces of teeth previously attacked.

The particular study under discussion was not designed to determine the minimum number of effective treatments. However, no marked difference in the amount of caries reduction was observed when the findings for the children who received 7 to 8 treatments were compared with those for the children who received 12 to 15 treatments.

Do fluoride treatments of half the teeth in the mouth affect the environment and caries experience of the untreated teeth in the other half of the mouth? In order to answer this question the caries experience of the teeth in a negative control group consisting of 326 children was studied concurrently with that in the treated group. Since the past caries experiences of the treated and of the control groups of children were quite similar, it seemed reasonable to expect that the incidence of dental caries during the study year would normally be approximately the same for both groups. Comparison of the caries experience in these two groups of children on the basis of number and percentage of teeth attacked by caries is presented in Table 3. The percentage caries attack rate (standardized for age) is 6.8 for the teeth in the untreated or right quadrants of the

mouths of the treated group and 7.0 for the teeth in either the right or the left quadrants of the mouths of the control group of children. Because of the similarity in these rates it was concluded that the effect of the fluoride treatment is exclusively local during the first year following treatment.

A summary of the major findings of this most recently reported study on the topical application of fluoride to the teeth is as follows:

1. The treatment described effected a 40 per cent reduction in the incidence of dental caries during the first year following treatment. The treatment was appreciably more effective in preventing caries in the upper than in the lower teeth.

2. The treatment was of questionable value in inhibiting caries extension on the non-carious surfaces of previously attacked teeth. There was no evidence that the treatment effected an arrest of active caries.

3. During the first year after treatment, the caries inhibiting effect was confined to those teeth to which the fluoride solution was topically applied.

Before proceeding to a discussion of the usefulness of the topical application of fluoride to the teeth, it must be admitted that at present the total experience with this method for obtaining reduction in the incidence of dental caries is very meager and merely sufficient to encourage further study. However, the results of these preliminary tests have given rise to the conviction that the effectiveness of this

TABLE 3

* Numerical average of the age-specific rates

type of therapy can be improved markedly. Therefore, in order to limit the present consideration of the relative usefulness of topically applied fluorides in post-war dental health programs, this discussion will be based on the pessimistic assumption that the current indications of the prophylactic effect of the two methods of fluoride therapy will be established at the current level of apparent effectiveness and that other more efficient methods will not soon be available for use.

It has been demonstrated by Dean and his coworkers⁵ that approximately 1 p.p.m. of fluoride in communal water supplies is associated with a 50 to 65 per cent reduction in the prevalence of dental caries. For the purposes of this discussion, this level of prophylactic effectiveness is accepted as the expected result of the purposeful adjustment of municipal water supplies to a fluoride concentration of 1 p.p.m. Under the foregoing assumptions it is obvious that fluoride added to water supplies is more effective in preventing dental caries than fluoride applied topically to the teeth. Furthermore, a program based on the addition of fluoride to municipal water supplies is far less costly and far less difficult to administer than one based on individual therapy. Nevertheless in considering a program for an over-all reduction of dental caries in this country, the topical application of fluoride to the teeth cannot, for several major reasons, be dismissed as only of academic interest.

First, in order to obtain the full caries-inhibiting effect of fluoride bearing waters, it is necessary that the individual depend on such supplies for his ordinary purposes of water consumption during the first 8 years of life, or during the period when the teeth (excepting third molars) are being calcified. Thus this method is of direct value to future populations only. On the other hand, the topical applica-

tion of fluoride affords a preventive measure for use on the teeth of present populations.

Second, if all municipal water supplies in this country were adjusted to contain 1 p.p.m. of fluoride, approximately one-third of the population would not be covered by this form of fluoride therapy. Among that third of the population dependent on private wells or other supplies for their source of water,⁶ the topical application of fluoride is a useful substitute method.

Third, since neither method of fluoride therapy is a complete dental caries prophylaxis, a periodic dental examination for the early detection and treatment of those teeth which become carious will continue to be an important health service. The topical application of fluoride to the teeth could be routinely administered with each periodic dental examination. This possibility, together with the desirability of treating teeth with fluoride soon after eruption, reduces the importance of the problem of multiple treatments. Since, for example, the eruption of the permanent teeth occurs largely during the age span 6 to 13 years, the treatment of each annual crop of newly erupted teeth would afford an opportunity to submit previously erupted teeth to renewed treatment. Furthermore, the ability to secure a concrete preventive service may constitute an important incentive for obtaining periodic dental examination and the early correction of carious and other dental defects.

There is at least a theoretical possibility that a few individuals will develop mottled enamel from fluorine-treated waters, whereas this result is not possible through the use of topically applied fluorine. However, this comparison will not be used here to discredit the former method of therapy and favor the latter. There is no evidence that 1 p.p.m. of fluoride in the

communal water supplies produces dental fluorosis of esthetic importance to the individual or that it produces deleterious effects of any health significance; it is known that higher concentrations produce both. However, the danger of overdosage is common to many of the forms of therapy in extensive use today. Therefore, an indictment of the fluorine treatment of waters on the basis of our present knowledge of the dangers of overdosage does not seem reasonable.

From the foregoing considerations, the general conclusion is that the topical application of fluoride to the teeth is very likely to afford a method of practical usefulness for reducing the incidence of dental caries in the populations of the post-war period.

SUMMARY

A review of the reported experience on the dental caries-inhibiting effect of topical applications of fluoride solution to the teeth has been presented. Present indications are that the incidence of dental caries can be reduced approximately 40 per cent by this method of fluoride therapy.

Although it is highly probable that a 50 to 65 per cent reduction in dental caries can be accomplished by the simple addition of 1 p.p.m. of fluoride to domestic water supplies, the topical application of fluoride to the teeth affords a useful adjunct or substitute method for obtaining a somewhat smaller reduction in the incidence of dental caries. There is a particular usefulness of the topical method of therapy to present populations and to that third of the population dependent on private wells for their water supplies.

Post-War Implications of Fluorine and Dental Health *

From the Viewpoint of Public Health Dentistry

ALLEN O. GRUEBBEL, D.D.S., M.P.H., F.A.P.H.A.

*Director, Division of Dental Health, Missouri State Board of Health,
Jefferson City, Mo.*

DENTAL health programs have been adjusted to meet the needs of wartime. When peace comes, public health dentistry should direct its energies toward two goals: (1) a wider distribution of dental care in proportion to the dental disease problem, and (2) the improvement of technics in dental disease control.

Generally speaking, programs for the promotion of dental health have thus far been based on health education and on early detection and treatment of dental defects. Although all dental diseases are of special interest to public health dentistry, dental caries has been given the greatest amount of attention by virtue of the fact that the majority of dental health programs have been directed primarily toward children and because dental caries is chiefly responsible for the loss of teeth in these younger age groups.¹ There are no immediate prospects that health education and corrective programs alone will solve the dental caries problem. If we were to attempt to do so, children would need to be given approximately six times the amount of dental service they now receive for the protection of permanent teeth, as suggested in the report

of the Hagerstown studies,² in addition to a considerable increase in the treatment of deciduous teeth. To institute such a program would require not only a greater number and a more equal distribution of dentists among the population but also health education and administrative facilities of considerable magnitude.

Public health dentistry has not heretofore been armed with an effective procedure for preventing dental caries; nevertheless, a number of dental health programs have been responsible for a material reduction in the number of untreated carious teeth and in the number of lost permanent teeth.^{3, 4, 5} It is important to point out, however, that these accomplishments were effected in relatively small populations; to obtain similar results for the majority of persons in any county or state would require a vast increase in public health and dental professional facilities. Present indications give us reason to believe that dental treatment service will continue to be an essential part of any caries control program. The amount of dental treatment service needed to control caries effectively in the future will depend on how successful we are in protecting teeth against caries. There is no satisfactory evidence to show that our past efforts in preventive dentistry have materially reduced the incidence or preva-

* Presented before the Oral Health Group of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

lence of caries; the same may be said for our attempts to protect teeth against caries by the use of the tooth brush and an adequate diet. Epidemiologic, chemical, and bacteriological studies indicate that the inhibiting effect of fluorine may provide us with the most effective caries control procedure thus far discovered.^{6, 7} It has been suggested that the most practical application of this new knowledge would be to add non-toxic doses of fluoride to a fluoride-free public water supply.⁸ It is interesting to speculate on how much the administration of a caries control program would be aided by applying this procedure in an area where fluorine is not now present in the water supplies. Laclede County, Mo., might well be taken as an example because it represents conditions which are common to many other counties in the state.

Laclede County did not have an organized dental health program prior to 1942. For a number of years this county had a peacetime ratio of 3,119 persons per dentist. The dental examination of 2,807 white children within the ages of 6-14 showed an observable caries experience rate (def rate)* of 334 decayed and filled deciduous teeth per 100 children and a dental caries experience rate in permanent teeth of 272 DMF teeth per 100 children; 7.2 per cent of the children had no observable caries experience in deciduous teeth, and 18.6 per cent of the children had no dental caries experience in permanent teeth. Of the deciduous teeth with a history of decay 65 per cent required fillings, 23 per

cent were indicated for extraction, and 12 per cent were filled. Of the permanent teeth with a history of decay 69 per cent required fillings, 7 per cent were lost, and 24 per cent were filled.

In attempting to develop a dental health program for this group of children, dental treatment services would need to be given major emphasis in order that the accumulation and the yearly increment of caries lesions might be corrected. Computations were made to determine how many working hours would be required for the dentists in Laclede County to correct the dental defects resulting from carious lesions, assuming, of course, that each child would submit to the required treatment. Consideration was only given to fillings, extractions, and special services such as pulpotomies and the construction of space maintainers to correct only those conditions which were the direct result of dental caries in deciduous and permanent teeth.

It was estimated that it would require 8,344 hours of dental treatment to correct the defects resulting from carious lesions in deciduous and permanent teeth. It was also estimated that the total working time of the 6 dentists in Laclede County for one year would amount to approximately 10,800 hours. In other words, it would require four-fifths of the working time of the 6 dentists in the county to take care of the dental needs of children the first year. These estimates typify the extent of our problem and clearly indicate that public health dentistry is badly in need of a weapon for effecting mass protection against dental caries. The use of non-toxic amounts of fluoride might provide at least a partial answer to our problem. For instance, from a purely theoretical standpoint the question might reasonably be asked: To what extent would the caries problem be altered if all of the Laclede County

* The symbol "def" represents a measurement of observable dental caries experience in deciduous teeth. The def rate is obtained by: the number of decayed deciduous teeth requiring fillings + the number of decayed deciduous teeth indicated for extraction + filled deciduous teeth \div the number of children examined $\times 100$ = observable dental caries experience rate per 100 children.

Lower case letters are used for the symbol "def" in contrast to the upper case letters DMF which represents dental caries experience in permanent teeth.

children had received the beneficial effects of fluoride?

Arnold compared the caries experience rates of Aurora, Ill., children, who used water containing 1.2 p.p.m. of fluoride, with the caries experience rates of the children living in Evanston, Oak Park, and Waukegan, and who used fluoride-free water. The comparison revealed that about six times as many Aurora children showed no dental caries experience and that the Aurora children had about a 60 per cent lower dental caries experience rate.⁹

By making a similar comparison with *Laclede County children, and assuming* that these children had used a domestic water containing approximately 1 p.p.m. of fluoride since birth, the Laclede County children might be expected to show a 60 per cent lower caries experience rate and six times as many children may have had no dental caries experience. If such conditions did exist, it is then estimated that it would only require approximately one-half of the working time of the 6 dentists in the county to correct the caries produced defects in deciduous and permanent teeth the first year. The dental caries problem would thus be brought within the range of a dental care program. In the case of Laclede County, for instance, 2 additional dentists would change the dentist-patient ratio so that 8 dentists would only be required to devote one-third of the working time to the 6-14 year age group instead of the actual circumstance whereby 6 dentists need to set aside four-fifths of their working time for this group of children.

There are, however, other factors to be considered in connection with the utilization of fluoride as a caries control procedure. It has been suggested that the addition of small amounts of fluoride, not to exceed 1 p.p.m., to fluoride-free public water supplies may be a practical and an efficient method of markedly inhibiting dental caries in

large group populations.¹⁰ Although the manipulation of public water supplies is a comparatively simple and proven method for protecting the public against disease, this procedure would only benefit persons living in cities or communities which have a public water supply. For example, in Laclede County there is at present one public water supply which is used by only 18.7 per cent of the people in the county. Thus, some means must be found to employ fluoride for the benefit of all the people.

Public health dentistry is charged with the responsibility of improving the *dental health of the public by employing* the most effective and efficient procedures possible. If it is shown conclusively that the addition of fluoride to water or food, or by the topical application of fluorine to teeth, produces a measure of protection against dental caries, this element should be used to the best possible advantage. On the other hand, public health dentistry is also obligated to protect the health of the people it serves and should not, therefore, use any toxic agent without adequate knowledge of its action and limitations. Reports of studies on this subject,^{11, 12} indicate that if fluoride is ingested in a concentration of less than 1 p.p.m. of water, no harmful effects have thus far been discovered.

Ample evidence apparently has been presented by competent investigators that a public water supply containing fluoride will inhibit caries.¹³ Much work still remains to be done to determine the proper application of this knowledge. Public health dentistry will have an important rôle in the development of new technics in public health practice if fluorine is used in dental caries control.

SUMMARY

Post-war objectives of public health dentistry should include a wider distribution of dental care and improved

technics in dental disease control.

Dental caries, one of the unsolved health problems, will not apparently be controlled adequately by health education and dental treatment service.

In an attempt to determine how much a caries control program would be aided by adding non-toxic doses of fluoride to domestic water supplies, rough estimates were made of the dentists' working hours which would be required to correct the dental defects caused by caries in children 6-14 years of age. Comparisons were made of the actual dental treatment requirements with the theoretical corrective needs if the expected benefit of fluoride were obtained.

Consideration was given to the importance of knowing the toxic effects of fluorine before this element is introduced into domestic water supplies.

The rôle of public health dentistry in utilizing fluorine in the caries control program was discussed.

Digest of the Discussion following the Fluorine Papers

Leo Remes, D.D.S., L.D.S., R.C.S.
(England), New York, N. Y.:

"In advocating the use of fluorine the epidemiologist, always seeking to apply measures which give promise of alleviating a public health hazard, may be within his province. However, as scientific men in the presence of as yet meager evidence, we should hesitate to advocate the universal use of this admittedly dangerous agent without further knowledge of its mode of action. We need to know something more about the rationale of fluorine's action in preventing caries; an acceptable hypothesis respecting the anti-enzymotic action of fluorine is still wanting. Whether fluorine acts by bathing the tooth in a fluoride bearing saliva, or by arriving at

the enamel rods via the putative lymph supply of the enamel are questions which not only may determine our therapeutics but they remain as valuable safeguards against the acceptance of potentially dangerous measures on empirical grounds. Without such safeguards much harm may ensue, and a great disservice be done to dentistry."

H. T. Dean, D.D.S., Bethesda, Md.:

"Universal fluorination of domestic water supplies was not advocated in my paper. In fact it was particularly stressed that two phases of this problem still await investigation:

1. General epidemiological studies of populations exposed for a long number of years to relatively high fluoride waters in order to

learn the effects, if any, of such fluoride intake on the community's general health.

2. An experimental test embracing human populations to learn whether the addition of 1 p.p.m. of fluoride (F) to a fluoride-free water will actually reduce the amount of dental caries in the community.

"Until these two crucial fields are adequately studied any general recommendation with respect to low fluorination of domestic water supplies would be premature and unwarranted.

"It is not essential that the mode of action of the fluorine be known before setting up the test studies. Preventive medicine utilized observed natural phenomenon as a basis for far reaching control measures years before the laboratory provided the 'scientific explanation' of the phenomenon. The conversion of Jenner's observation of the protective influence of vaccinia virus in smallpox prevention rested on the purest of empirical grounds for a century. For generations scurvy and malaria were effectively controlled before either their etiology or the mode of action of the prophylactic agent was known."

John Oppie McCall, D.D.S., New York, N. Y.:

"I would like to ask Dr. Gruebbel if there has been any attempt to intensify or prolong the action of sodium fluoride when applied to the tooth surface. It is common practice, when silver nitrate is applied, to reduce it with formalin or eugenol. I should like to ask if there is any way of rendering the fluoride less soluble, after its application to the tooth, by using lime water or other compound."

Dr. Gruebbel replied that he had made no such experiment.

James M. Dunning, D.D.S., Lieut. (D.C.) U.S.N.R., New York, N. Y.:

"As evidence that preventive methods centered on oral hygiene and early treatment have produced positive re-

sults, may I say that recent studies of the Metropolitan Life Insurance Co. home office force show a decrease over fifteen years of approximately 1½ missing teeth per person in the age groups between 30 and 50. This decrease seems chiefly due to the preventive service started by Hyatt."

Allen O. Gruebbel, D.D.S., M.P.H., Jefferson City, Mo.:

"Dr. Dunning's remarks are not in conflict with the statements in my paper. It is admitted that dental programs have accomplished good results for a number of relatively small population groups, but there is no evidence that such has been the case for the public in general. The paper contained the following statements: 'There are no immediate prospects that health education and corrective programs alone will solve the dental caries problem. . . . Public health dentistry has not heretofore been armed with an effective procedure for preventing dental caries; nevertheless, a number of dental health programs have been responsible for a material reduction in the number of untreated carious teeth and in the number of lost permanent teeth. It is important to point out, however, that these accomplishments were effected in relatively small populations; to obtain similar results for the majority of persons in any county or state would require a vast increase in public health and dental professional facilities.'"

James M. Dunning, D.D.S., Lieut. (D.C.) U.S.N.R., New York, N. Y.:

"Were observations made of the gingivae and mucous membranes of your cases after treatment, and if so, were any evidences of damage, toxic or otherwise, found?

"(I missed the first part of Dr. Knutson's paper, but was told he did not cover this point in his main text. If he

did not, his answer (no damage) seems an interesting addition to his story.)”

*John W. Knutson, D.D.S., Dr.P.H.,
Minneapolis, Minn.:*

“The mouths of most of the children in our study group were observed twice a week during the eight week treatment period. There were no indications that the fluoride solution produced gingivitis or other signs of toxic damage to the soft tissue of the mouth, or to the gingivae surrounding the treated teeth.”

*Harry S. Thomson, D.M.D., Toronto,
Ont.:*

“I am very happy to be present at this meeting and to hear these reports. I must, however, express my feeling of alarm and grave concern over the possibility of too early publicity being given to findings based on, as yet, limited investigations, but which, from a news standpoint might be considered spectacular and sensational. I do hope that very creditable research such as this can be held down to purely scientific discussion until investigation by other workers reveals the full physiological action of the fluorides, from both a beneficial and an opposite effect, on the entire organism.

“We can all visualize that some energetic young reporter might take ad-

vantage of this preliminary scientific report, and the remarks made in a joking way about incorporating fluorides in ice cream and chewing gum, and make it a newspaper story that would put *his* name on the front page of the city papers, but which would be a source of great annoyance to the research workers and dental health officials.

“I make a strong plea that this matter be considered solely from a scientific point of view by the group here assembled, until further work is accomplished and reports are issued.”

*J. A. Salzmann, D.D.S., New York,
N. Y.:*

“It is gratifying to know that public health workers are following epidemiologic procedures in their attempts to control dental decay. This approach should be distinguished from efforts to ascertain causation which many research workers are pursuing, and from preventive dentistry which is nothing more than treatment of manifest dental decay. Fluorine holds forth great promise. However, we should be circumspect in our statements to the lay press, lest we arouse premature enthusiasms and popular fads and so endanger the good that may eventually come from this work.”

Correlation of *in vitro* Sulfonamide Resistance of the Gonococcus with Results of Sulfonamide Therapy^{*†}

CHARLES M. CARPENTER, M.D., F.A.P.H.A., AND
HELEN ACKERMAN

University of Rochester, School of Medicine and Dentistry, Rochester, N. Y.

AND

MILLARD E. WINCHESTER, M.D., F.A.P.H.A., AND
JANE WHITTLE

Glynn County Board of Health, Brunswick, Ga.

PREVIOUS studies have demonstrated that *in vitro* the gonococcus acquires resistance to gradually increased concentrations of sulfanilamide, sulfapyridine, sulfathiazole, and sulfadiazine.¹⁻⁴ It has been shown, furthermore, that induced resistance of an organism to one sulfonamide compound usually increases resistance to other derivatives of sulfanilamide.^{3,5} These observations, together with an apparent decrease in the therapeutic efficacy of sulfonamides in gonorrhea, suggested the investigation of a possible correlation between the laboratory and clinical findings. Information as to the prevalence of sulfonamide resistant strains of the gonococcus in a community following the widespread use of sulfonamides would in addition provide data of epidemiologic significance. Cohn and Seijo⁶ have recently reported a direct relationship between the therapeutic

efficacy of sulfathiazole in patients with gonococcal infection in New York City, and the susceptibility of the patient's strain of gonococcus to the drug *in vitro*.

The present report records the results of treatment with sulfathiazole on 105 patients with gonococcal infection and the *in vitro* behavior to sulfanilamide and sulfathiazole of the strains of the gonococcus isolated from those patients. This study was carried out at the Glynn County Board of Health, Brunswick, Ga.

MATERIALS AND METHODS

Patients with symptoms of uncomplicated urethritis of cervicitis reporting at the venereal disease clinic were examined for evidence of gonococcal infection. The film and cultural methods were used to verify the diagnosis of the disease. Those from whom the gonococcus was isolated were treated with a single course of therapy consisting of 20 gm. of sulfathiazole administered in one of the two following manners: 3 gm. daily for 6 days and 2 gm. on the 7th day or 4 gm. daily for 5 days. In a few instances sulfapyrazine was sub-

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

† This study was carried out in cooperation with the Division of Venereal Diseases, U. S. Public Health Service, Washington, D. C.

stituted for sulfathiazole. The patients returned to the clinic for examination once a week for at least 3 weeks, and at each visit films and cultures were again taken. A series of three negative bacteriologic examinations together with the absence of clinical evidence of disease comprised the criteria of cure. Thus, patients responding to one course of therapy were considered "cured," and those requiring additional treatment were designated "failures." The 105 patients included in this study were classified according to race and sex as follows: Negro, 79; white, 26. The Negroes comprised 54 males and 25 females; the white patients, 13 males and 13 females. Included in this group were only those patients with no history of previous treatment with sulfonamide compounds.

The strain of gonococcus isolated from each patient before treatment was tested *in vitro* for growth in blood-broth media containing sulfanilamide and sulfathiazole. As a rule, the tests were carried out as soon as possible after isolation, the strains examined for the most part being between the 5th and 10th generations. In addition to the 105 strains of the gonococcus recovered from this group of patients, similar tests were made on 109 strains isolated in this same community. The observation period of the study extended from May 1, 1942, to August 1, 1943.

The medium was prepared in the following manner. Sulfanilamide to yield final concentrations of 5, 10, 20, and 40 mg. per cent was added to Douglas's broth containing 0.05 per cent each of sodium phosphate and sodium nitrate. After sterilization in the autoclave at 121° C. for 10 minutes, 5 ml. of defibrinated lapine blood were added to each 100 ml. of the medium. The sulfathiazole broth was prepared in a similar manner except that concentrations of 1, 2, 5, and 10 mg. per cent of the drug were employed.

Five ml. of medium in test tubes were inoculated with 0.1 ml. of a 24 hour Douglas's broth culture of the strain to be tested. A tube of blood broth without drug was also inoculated to serve as a control. After 48 hours of incubation at 37° C. subcultures were made to "chocolate" agar plates which were similarly incubated, and the presence or absence of growth was recorded. When growth occurred in any tube containing drug, the strain was designated "resistant." If no growth was detected, the strain was considered "nonresistant." The minimal concentrations of 5 mg. per cent and 1 mg. per cent of sulfanilamide and sulfathiazole, respectively, were selected because they were significantly higher than the concentrations which were bactericidal for strains of the gonococcus isolated from patients readily cured with a single course of sulfonamide therapy.

RESULTS

Of the 105 selected patients with gonococcal infection from whom *Neisseria gonorrhoeae* was isolated prior to sulfonamide therapy, 88, or 84 per cent, were "cured" with one course of 20 gm. of either sulfathiazole or sulfapyrazine. The remaining 17, or 16 per cent, failed to be cured with the same amount of drug.

Seventy-seven strains of the gonococcus, 87.5 per cent, isolated from the 88 patients designated as "cured" failed to grow *in vitro* in any of the concentrations, 5, 10, 20, and 40 mg. per cent sulfanilamide or in concentrations of 1, 2, 5, and 10 mg. per cent sulfathiazole. The remaining 11 strains, 12.5 per cent, on the other hand, resisted the action of one or both drugs *in vitro*.

Thirteen strains of the gonococcus, 76.5 per cent, recovered from 17 patients that failed to be cured likewise remained viable when exposed to the

November, 1942–January, 1943	45	33	12	26.7
February, 1943–April, 1943	69	46	23	33.3
May, 1943–July, 1943	54	22	32	59.3
Total	214	140	74	34.6

effect of the drugs *in vivo* and the resistance of the specific organism *in vitro* showed that of 81 patients infected with "nonresistant" strains, 77, 95 per cent, were "cured," but that of 24 patients infected with "resistant" strains, only 11, 46 per cent, were "cured" with an equivalent amount of the compound (Table 1).

Of a total of 214 strains of the gonococcus isolated prior to treatment at Brunswick, Ga., during a 15 month period from May 1, 1942, to August 1, 1943, and tested for sulfonamide resistance, 74, or 34.6 per cent, were "resistant" to sulfanilamide and sulfathiazole *in vitro*. Of greater significance, however, is the finding that only 15.2 per cent of these strains tested dur-

DISCUSSION

Cohn and Seijo⁶ working with 107 strains of the gonococcus isolated from 101 patients in New York City have reported that 100 per cent of the patients with "nonresistant" strains were cured, but only 18 per cent of the patients with "resistant" strains recovered. In our study, 95 per cent of the patients with "nonresistant" strains responded favorably to sulfonamide therapy as well as 46 per cent of the patients with "resistant" strains. Thus in the group reported by Cohn and Seijo, only 3 of 17 patients with "resistant" strains of the gonococcus were cured, whereas in our group, 11 of 24 patients with "resistant" strains recovered. A valid comparison of the results obtained

in the two studies cannot be made because each patient of Cohn and Seijo received during the first course of therapy only a total of 14 gm. of drug. Our patients, on the other hand, were given a total of 20 gm. each.

The investigation of the resistance *in vitro* of recently isolated strains of the gonococcus to concentrations of sulfonamide compounds comparable to those obtained in the blood of patients after sulfonamide therapy has provided information of value in shedding light on the future course of sulfonamide therapy in gonorrhea. Evidence has been accumulated to indicate that the extensive use of sulfonamide compounds, chiefly sulfathiazole, for the treatment of gonococcal infection within a period of 15 months has markedly increased the prevalence of "resistant" strains in the community in which the study was carried out. This finding may possibly be attributed to the elimination of a high percentage of the "nonresistant" strains by chemotherapy, as well as to the development of "resistant" strains from exposure to the drugs *in vivo*. Inasmuch as the gonococcus acquires resistance to sulfonamides *in vitro*, undoubtedly the organism becomes resistant to the drugs *in vivo*.

The marked increase in the number of "resistant" strains isolated from untreated patients at the venereal disease clinic is striking. It is known that during the period of observation numerous patients in the community obtained sulfathiazole from local pharmacists presumably for the treatment of gonococcal infection. Therefore, self-treatment may have cured many patients infected with "nonresistant" strains of the gonococcus. Thus a proportion of patients attending the clinic may have comprised those who failed to cure themselves. It must be pointed out, however, that every effort was made to exclude previously treated patients from the study in order to eliminate strains

of the gonococcus known to have been exposed to sulfonamides.

Routine tests for the sulfonamide resistance of a strain of gonococcus *in vitro* are as yet impractical because of the time and expense involved. The present study points out, however, one of the difficulties encountered in carrying out with sulfonamide therapy an intensive program for the community control of gonorrhea.

It is interesting to speculate on whether "resistant" strains of the gonococcus were distributed in man previous to the era of sulfonamide therapy, or whether strains of the organism have acquired resistance as a result of contact with the drug. Further investigations including studies of strains isolated prior to the "sulfonamide era" may answer this question.

SUMMARY

The *in vitro* response to sulfathiazole and sulfanilamide of 105 strains of *Neisseria gonorrhoeae* has been correlated with the clinical responses of the patients from whom the organisms were isolated.

Of the group of patients from whom "nonresistant" strains were isolated, 95 per cent were "cured" in 5 days with 20 gm. of sulfathiazole. On the other hand, only 46 per cent of the group with "resistant" strains responded to an equivalent amount of sulfonamide therapy.

An increase in the prevalence of sulfonamide-resistant strains of *Neisseria gonorrhoeae* from 15 to 59 per cent in 15 months was observed in Glynn County, Ga., from May, 1942, to August, 1943, following the extensive use of sulfonamide drugs as a part of a special program for the control of gonorrhea.

Health Workers Now Subject to W.M.C. Employment Stabilization Program

The War Manpower Commission, Washington, has announced that physicians, dentists, veterinarians, sanitary engineers, and nurses who are salaried employees in essential or locally needed activities are hereafter subject to the same provisions of any employment stabilization program as applies to other workers in such activities. Such professional employees may not change their jobs without securing statements of availability from the U. S. Employ-

ment Service or being referred to new jobs by this Service. It is understood that the U.S.E.S. will make referrals of such employees only after consulting the state chairman of the Procurement and Assignment Service. The W.M.C. state directors may delegate the duty of referring such employees to new jobs to the state and local offices of the Procurement and Assignment Service if this delegation is approved by the regional W.M.C. director.

A Proposed Method for Control of Food Utensil Sanitation*

RECOGNIZING a demand on the part of health officials for a method of determining whether or not food utensils have been rendered relatively free from bacteria by the ordinary procedures followed in washing and disinfecting food utensils in public eating and drinking establishments, consideration has been given to standardizing a test for this purpose.

Many health departments now are using bacteriological methods of one kind or another for the testing of utensils for bacterial content. The technics in use include that suggested by a subcommittee of the Committee on Research and Standards of this Association as published in the *Year Book for 1936-1937*,¹ an adaptation of the swab-rinse test for milk plant equipment which appears in the 8th Edition of *Standard Methods for the Examination of Dairy Products*² and other modifications proposed by individuals.

Your subcommittee has given serious thought to the basic problems involved, with a view either of developing improved methods or of making a current revision of the technic proposed in 1936 for use until better methods are investigated, standardized, and made available.

As in other problems of this kind, the ideal procedure would be to determine the presence or absence on the utensils of organisms pathogenic to man. The available procedures for identifying specific pathogenic bacteria are too time-consuming and too expensive for

use in routine work of this kind. Furthermore, if examinations for all pathogenic organisms were made, and they were found to be absent on the particular utensils examined, there could be no assurance that they were not present on other utensils not examined at the time, or that they would not be present another day when a disease carrier happened to patronize the establishment from which the utensils were obtained.

Another possibility would be to examine the utensils for the presence or absence of some test organism, preferably one normally present only in the upper respiratory tract of man. In addition, perhaps an examination might be made for an organism indicating finger contamination of the utensil.

In a quest for a test organism from the upper respiratory tract, Dick and Hucker³ report finding an organism identified as *Streptococcus salivarius* on the lips of 100 unselected individuals. They also report that, without exception, each of these 100 persons deposited streptococci on the rims of sterile glasses in drinking sterile liquid therefrom. They found that the organisms survived on the rims of drinking glasses in most instances for 48 hours or more. They suggest a technic for making a presumptive test for this organism. Considerable comparative routine laboratory work needs to be done to confirm these results and to demonstrate the relative advantages and disadvantages of this test before it can be considered for standardization for routine use.

Health departments have used the

* Progress Report of the Subcommittee on Food Utensil Sanitation of the Committee on Research and Standards for 1943.

test for coliform organisms as a possible indication of finger contamination. Some workers report that the results duplicate those obtained by the swab-rinse plate count technic. However, others report an appreciable percentage of positive coliform findings in instances in which bacteria counts were acceptable. Sufficient work has not been done to determine whether or not the use of the coliform test is advantageous.

An examination of the literature reveals that the test most commonly used to date for the examination of supposedly sterilized food utensils has been some form of the swab-rinse plate count technic. There are many variations in the details of the procedures used, possibly because the test is in a formative stage and no technic has been adopted as standard by the Association. The common basis for these varied technics is the previously mentioned standard proposed in 1936 by the former subcommittee. In addition to a swab-rinse plate count method, this included a rinse plate count technic in the performance of which such articles as forks and spoons were placed in a fruit jar containing sterile water and shaken, after which a standard plate count was made on the rinse water.

It is recognized that this general method of testing has weak points. It is difficult if not impossible to remove all or a fixed percentage of the bacteria from the surface such as the rim of a glass. Also the percentage of organisms transferred from the cotton swab to the rinse solution is variable. Furthermore, the rinse solution is not a favorable medium for maintaining viability, so plating must be done within a few hours, otherwise marked reductions in bacterial counts result. In addition there are the well known variables of the standard plate count technic.

However, notwithstanding these acknowledged weaknesses, the practical use of the test has shown that high

counts generally are associated with the use of careless methods in washing and disinfecting utensils that would permit the passage of pathogenic organisms to the supposedly cleansed and sanitized utensils if such organisms happened to be present on the utensils at the beginning of the process or if the organisms are present in the wash or rinse waters. Of course, a test result indicating the presence of organisms in small numbers gives no assurance that pathogenic organisms may not be present. However, a low count does indicate the use of rather careful methods in washing, sanitizing, and handling the utensil up to the time the test is applied. The test also is useful in process-sampling by examining utensils at various stages of the process of rinsing, washing, sanitizing, handling, and storage.

Comparing this method with tests used in similar fields of public health work, the standard plate count, with all its faults, has been useful in the early stages of the public health control of water supplies to indicate gross contamination and in the supervision of milk supplies to indicate gross carelessness in the methods used in the production, processing, and handling of milk. Other and more specific tests are assuming increasing importance with the improvement of water and milk supplies.

The work in restaurant sanitation generally is at the early stage at which a test such as the swab-rinse plate count may be useful. By the time some of the worst conditions have been improved it is possible that new and more specific tests may be devised.

As a starting point, this subcommittee has revised the swab-rinse plate count technic in the light of the experience of recent years, and submits it for further constructive criticism before proposing its acceptance by the Association as a standard test. It is recognized that this technic will not give the highest possible count but is intended to give as nearly

as possible a comparable count. Suggestions may be sent to the committee through the Association office, or

directly to the Chairman, W. D. Tiedeman, New York State Department of Health, Albany, N. Y.

TECHNIC FOR THE BACTERIOLOGICAL EXAMINATION OF FOOD UTENSILS AS
REVISED AND PROPOSED FOR ADOPTION AS A STANDARD METHOD BY THE
SUBCOMMITTEE ON FOOD UTENSIL SANITATION OF THE COMMITTEE ON
RESEARCH AND STANDARDS OF THE AMERICAN PUBLIC HEALTH
ASSOCIATION IN OCTOBER, 1943

Apparatus and Materials—Sterile Petri dishes, sterile 1 ml. pipettes, standard tryptone glucose extract agar (without milk), sterile forceps or scissors, sterile cotton swabs on standard wooden applicator sticks, and sterile swab containers. Satisfactory containers consist of screw-cap swab bottles 23 by 70 mm. or 16 x 100 mm. bacteriological test tubes, with cork or rubber stoppers. Other tubes, vials or wide mouth bottles, $\frac{1}{2}$ to 1 in. inside diameter and $2\frac{1}{2}$ to $3\frac{1}{2}$ in. high, and with mouth not less than $\frac{1}{2}$ in. in diameter, may be used. Cotton plugs are not satisfactory. The swab holder may be attached to the cap or stopper, or separate dry swabs may be carried in glassine envelopes or sterile containers providing protection against contamination. The swab on the wooden applicator shall be of firmly twisted cotton, approximately $\frac{3}{16}$ in. in diameter and $\frac{3}{4}$ in. long.

Buffered Distilled Water—The purpose is to secure a sterile solution that is non-toxic to bacteria. Prepare the phosphate buffer solution as directed in detail on page 126 of *Standard Methods for the Examination of Dairy Products*, 8th Edition (1941). Briefly, this is done by dissolving 34 gm. of potassium di-hydrogen phosphate in 500 ml. of distilled water, adding about 175 ml. of a normal sodium hydroxide solution, diluting to 1 liter with distilled water, adjusting this solution to pH 7.2, and diluting 1 ml. of this stock solution to 800 ml. with boiled and cooled distilled water. If the utensils to be

swabbed are likely to contain residual chlorine, add 4 ml. of a 0.1 N sodium thiosulfate solution to the 1 ml. of stock solution before diluting it to 800 ml.

Distribute the diluted solution in the swab containers in amounts that will provide, after sterilizing in the autoclave at 121° C. for not less than 20 minutes, exactly 1 ml. for each utensil to be examined per swab; e.g., 4 ml. for 4 utensils, 5 ml. for 5 utensils, etc. The containers should be autoclaved either with the swabs in place or in separate containers and the caps slightly loosened.

Collecting Samples—Utensils to be examined shall include at least glasses, cups, and spoons, if used, and at least 4 of each shall be selected at random from the shelves or other places where clean utensils are stored. If a direct check of the dishwashing methods is desired, utensils should be selected from those recently washed. Care shall be taken to prevent contamination by handling during sampling.

Use 1 swab for each group of 4 or more similar utensils. Take the swab from a freshly opened container of dilution water or dip a sterile swab, if separate, in such dilution water, and squeeze it against the side of the container so as to remove excess water, leaving the swab moist but not wet. Rub the swab slowly and firmly three times over the significant surfaces of 4 or more similar utensils. After swabbing each utensil, return the swab to the container of dilution water, rotate the swab in the dilution water, and

press out the excess water against the side of the container before swabbing the next of the 4 or more utensils in the group.

The significant surfaces of utensils consist of the upper $\frac{1}{2}$ in. of the inner and outer rims of cups and glasses and the entire inner and outer surfaces of the bowls of spoons. If it is desired to examine forks and surfaces of dishes, etc., the area to be swabbed should include the entire inner and outer surfaces of the tines of forks, and the inner surfaces of plates and bowls over an area of approximately 4 sq. in. that would come in contact with the food. The area to be swabbed on plates and bowls is to be estimated.

After completing the swabbing of all utensils in the group of 4 or more, replace the swab in the container of dilution water. Use a new swab container for the next group of utensils. Keep the containers iced while in transit to the laboratory, and plate the dilution water samples as soon as possible, preferably within 4 hours of swabbing.

Laboratory Procedure—Break the swab stick just above the cotton with sterile forceps, or cut with sterile scissors, allowing the cotton swab to drop into the diluent, where subsequent agitation should thoroughly disentangle the cotton which should be allowed to remain in the container while making transfers. Shake the swab container rapidly, making 50 round trip excursions of 4 to 6 in. with the container in one hand, striking the palm of the other hand at the end of each cycle, and completing the whole in about 10 seconds. Shaking machines may be used for time intervals found to disintegrate the cotton swab in a manner equivalent to the

prescribed hand method. Transfer 1 ml. of the dilution water to a sterile Petri dish. Add approximately 10 ml. of melted standard tryptone glucose extract agar (without milk), mix, incubate for 48 hours at 35° to 37° C., and count as in making a Standard Plate Count. Avoid slight increases in temperature above 37° C., because they materially lessen the number of visible colonies that will develop. Report the count as the average plate count of organisms removed per utensil surface examined. For example, if 4 glasses are swabbed, if 1 ml. of the 4 ml. of dilution water is plated and if 56 colonies are counted after incubation, record the average plate count per glass surface as 56.

Laboratories not conforming fully with this procedure should have comparative evidence to show that the variations used give comparable results.

Interpretation—The average plate count per utensil surface examined should not exceed 100. Higher counts are presumptive evidence of inadequate cleansing or bactericidal treatment, or of recontamination by handling or during storage. Judgment should be made on the basis of repeated sampling.

Serological Relationships within the Poliomyelitis Group of Viruses*

CLAUS W. JUNGEBLUT, M.D.

*Department of Bacteriology, College of Physicians and Surgeons,
Columbia University, New York, N. Y.*

EARLIER reports from this laboratory^{1, 2} have described the adaptation of two strains of poliomyelitis virus (SK, MM) from monkey or man to albino mice by means of intermediary passage through cotton rats or hamsters. The resulting mouse viruses were identified by serological tests which demonstrated neutralization of both murine strains by immune sera prepared against simian poliomyelitis virus; on the other hand, neutralization of simian virus could not be obtained by antisera prepared against murine virus. Whatever immunological relationship existed between simian and murine virus was therefore non-reciprocal in character.

It seemed of interest to continue the study of these rodent viruses by immunological methods in two further directions. First, to compare the mouse-adapted strains among themselves for any relationship that might become apparent in cross-neutralization tests; second, to determine, by cross-neutralization, their immunological position in relation to Theiler's virus of spontaneous mouse encephalomyelitis. Since earlier experience^{2, 3} had already demonstrated a certain degree of overlapping in serological reactivity between both murine strains (SK, MM) and antiserum prepared against

Theiler's virus, the neutralization tests were planned in such a way as to permit of a quantitative interpretation of the data.

EXPERIMENTAL WORK

A brief description of the methods used in carrying out these neutralization tests follows:

Virus—The three rodent viruses (SK, MM, Theiler GDVII) were maintained by serial intracerebral passage in young Swiss albino mice. Repeated titrations at periodic intervals showed little fluctuation in potency, except for Theiler's virus which acted irregularly on intraperitoneal injection during the summer months. The experiments were therefore suspended during that time of the year. Only virus freshly harvested from completely paralyzed mice was used for neutralization tests.

Immune sera—Monovalent immune sera against the three rodent viruses (SK, MM, Theiler) were prepared in rabbits. Live virus (10 per cent brain suspensions) was injected intravenously and intraperitoneally, twice a week, in slowly increasing doses ($\frac{1}{2}$ ml. to 2 ml., i.v.; 5 ml. to 20 ml., i.p.) over a period of 1 month or longer. When trial sera obtained 10 days after the last immunizing injection showed a satisfactory neutralizing titer, the animals were bled out. Sera of uniformly high potency were selected and pooled, according to virus, for use in the neu-

* Aided by grants from the Dr. Philip Hanson Hiss, Jr., Memorial Fund, the Warner Institute for Therapeutic Research, and anonymous donors.

Numerator = number of mice paralyzed. Denominator = number of mice injected. For definition of potency of serum and titer of virus—see text.

tralization tests. A hyperimmune serum preparation (pseudoglobulin fraction) against simian virus, produced by immunization of horses with monkey poliomyelitis virus (RMV strain), was obtained through the courtesy of Dr. J. Toomey. According to Toomey's published data⁴ this serum was capable of inactivating at least 50,000 minimal paralytic doses of simian virus as determined by intracerebral tests in rhesus monkeys.

Neutralization test—The test was carried out by adding virus to serum in definite proportions and injecting the mixtures, after incubation for 1 hour at 37° C., into groups of from 3 to 6 mice. The injections were made by either the intracerebral or the intraperitoneal route. In intracerebral tests with SK, MM, and Theiler's virus, 0.2 ml. of undiluted serum and 0.2 ml. of progressive virus dilutions were combined, and a volume of 0.03 ml. of the mixture was injected into individual mice. In intraperitoneal tests with SK and MM virus, 1 ml. of serum or serum dilution was combined with 1 ml. of virus dilution and a volume of 0.2 ml. of the mixture was injected into individual mice; for intraperitoneal tests with Theiler's virus the amounts were doubled, i.e., 2 ml. of serum were combined with 2 ml. of virus and the individual inoculum was 0.4 ml. Each test was accompanied by an adequate number of controls in which normal rabbit serum was substituted for immune serum, the technic otherwise remaining the same.

Interpretation of results—All injected mice were carefully observed for a period of from 2 to 3 weeks and the incidence of paralysis was recorded. With all three viruses paralysis was practically always followed by death. Deaths without preceding symptoms were noted on rare occasion, more often with Theiler's virus than with SK and MM virus. If these isolated deaths

occurred at irregular intervals, the animal was eliminated from the entire count; the number of such eliminations was negligible. Neutralization was arbitrarily graded on the basis of the following criteria: 0 to 33⅓ per cent paralysis = complete neutralization, 34 to 66⅔ per cent paralysis = partial neutralization, 67 to 100 per cent paralysis = no neutralization. Endpoints of serum potency were calculated on the basis of the largest amount of virus in combination with the smallest amount of serum which yielded complete neutralization. Such endpoints were usually quite sharp; occasionally, however, the activity of a serum dropped irregularly over a range of virus dilutions. The titer of each virus was gauged by the highest dilution which caused from 80 to 100 per cent paralysis in the control animals. By recording the antiviral potency of a given serum, in terms of complete neutralization against multiple paralytic doses of a given virus, it became possible to arrive at a simple quantitative estimation of levels of neutralization for the several virus-serum systems. The original records, most of which represent pooled data from repeated tests, are given in Tables 1 to 3. The quantitative estimates are shown graphically in the attached diagram.

The above data which are based on a total in excess of 1,600 mice, more than 1,100 of which were used for the titration of immune sera and more than 500 for control purposes, reveal some puzzling facts. It will be observed, for instance, that SK and MM virus, in intracerebral tests, were cross-neutralized by their corresponding antisera at similar levels; intraperitoneal tests, on the other hand, show that in spite of marked overlapping in the immune reaction, each virus was best neutralized by its homologous antiserum. Intracerebral tests furthermore indicate that SK virus was not neutralized by Theiler

QUANTITATIVE NEUTRALIZATION OF 3 RODENT POLIOMYELITIS VIRUSES BY
HOMOLOGOUS AND HETEROLOGOUS ANTISERA

antiserum, in contrast to MM virus, which was, markedly affected by the same serum; in intraperitoneal tests, however, both viruses were inactivated by Theiler antiserum, although to various degrees. These latter reactions appear to be strictly unilateral, for Theiler's virus, in intracerebral as well as intraperitoneal tests, remained com-

pletely refractory to neutralization by antisera against either SK or MM virus and showed only partial inactivation when tested intraperitoneally with simian hyperimmune serum. Interestingly enough, analogous unilateral reactions are encountered again when one recalls the relationships of SK and MM virus with simian poliomyelitis

TABLE 3
Neutralization of Theiler's Mouse Encephalomyelitis Virus by Homologous and Heterologous Antiviral Sera in Intracerebral and Intraperitoneal Tests

Antiviral Sera		Intracerebral Tests								Intraperitoneal Tests			
		Virus Dilutions							Potency of Serum	Virus Dilutions			Potency of Serum
		10 ⁻¹	10 ⁻²	10 ⁻³	10 ⁻⁴	10 ⁻⁵	10 ⁻⁶	10 ⁻⁷		10 ⁻¹	10 ⁻²	Titer of Virus

virus. Thus, both murine strains were inactivated, intracerebrally as well as intraperitoneally, by anti-poliomyelitis monkey virus serum, while antisera prepared with either SK¹ or MM⁵ murine virus were devoid of any neutralizing power against simian virus (SK, RMV, Aycock) in intracerebral monkey tests; similarly, Theiler convalescent mouse serum is said to be without any effect on simian poliomyelitis virus.⁶ In other words, monkey (or human) poliomyelitis virus and Theiler's virus of mouse encephalomyelitis, emerge as highly specialized infectious agents which yield to complete inactivation only by contact with their homologous antisera, whereas the two mouse-adapted strains of human poliomyelitis virus (SK, MM) engage in reciprocal interaction between themselves in addition to non-reciprocal interaction with both Theiler's virus and simian poliomyelitis virus.

DISCUSSION

The foregoing observations suggest a relatively simple immunological structure for simian poliomyelitis virus as well as for Theiler's virus of mouse encephalomyelitis. By contrast, the two mouse-adapted strains of human poliomyelitis virus (SK, MM) evidently represent highly complex antigenic mosaics, including major and minor receptors, some of which seem to function like haptenes. It appears furthermore that different methods of testing may yield different results. Thus, intracerebral tests gave evidence of group- (or species-) specific and intraperitoneal tests of strain- (or type-) specific inactivation of virus. It therefore seems reasonable to assume the presence in the virus molecule of components, with varying degrees of specialization, associated, on the one hand, with virus multiplication in nervous tissue and, on the other, with virus invasion by peripheral channels.

There is evidence to show that the peripherally acting component can deteriorate and become silent in the pathogenic sense, for immunization with SK tissue culture virus, harvested from remote *in vitro* generations which were no longer infective by peripheral routes (intraperitoneal, nasal, feeding), produced an antiserum capable of neutralizing SK virus, in both intracerebral and intraperitoneal tests, at levels identical with those observed with antiserum prepared with peripherally infective SK mouse passage virus.

The available data mark the two murine strains (SK, MM) as separate but closely related viruses in which homologous antigens are blended with heterologous antigens. It is also clear that both viruses have incorporated in them certain accessory fractions peculiar to simian poliomyelitis virus and to Theiler's virus.* The picture thus presented leads to an impression that human poliomyelitis virus and Theiler's virus may be natural variants of a common viral root, whereas the experimentally adapted murine viruses represent hybrid strains which occupy a position somewhere between these two fixed borders. It is probable that in such a scheme MM murine virus lies closer to Theiler's virus than does SK murine virus. Inclusion of the several viruses referred to, i.e., human, human-murine, and Theiler, in one family of intrinsically related viral agents under the designation of "poliomyelitis group"—originally proposed by us because of the variability in biological characteristics of the respective viruses³—appears therefore further justified in the light of the antigenic analysis just

* Recent observations by Melnick⁷ which have failed to demonstrate any reaction between SK murine poliomyelitis virus and Theiler antiserum in complement-fixation tests are in agreement with the results of our intracerebral but not intraperitoneal neutralization tests. It is possible that neutralization measures immunological reactivity *in vivo* more delicately than what is indicated by complement-fixation *in vitro*.

reported. The proposed unification is based on principles similar to those that have governed recent efforts to consolidate in one "encephalitis group" certain encephalitogenic viruses which likewise engage in reciprocal and non-reciprocal immunological interaction.^{8, 9} More particularly, it serves to substantiate an empirical classification, advanced by Gard¹⁰ essentially on morphological grounds, which groups human, murine, and porcine strains of poliomyelitis virus under the same term as proposed here.

CONCLUSIONS AND SUMMARY

Cross-neutralization tests between two mouse-adapted strains of human poliomyelitis virus and Theiler's virus of mouse encephalomyelitis and corresponding antiviral immune sera revealed overlapping reactions of various degrees between the three viruses. The overlapping reactions, in some instances were reciprocal, in others non-reciprocal

in character. Different results were obtained with intracerebral and intraperitoneal methods of testing, the former giving evidence of group-specific, the latter of strain-specific virus inactivation. The immunological data are discussed in their bearing on the position of the experimentally adapted murine strains in relation to Theiler's virus, on the one hand, and human poliomyelitis virus, on the other.

The Problem of Industrial Noise*

PAUL E. SABINE, PH.D.

Director, Riverbank Laboratories, Geneva, Ill.

EXPOSURE to excessive noise is a part of the price that modern man pays for a highly mechanized civilization. The major contributions of science to the solution of the noise problem are through the marshalling of data showing that the resulting annoyance is a positive menace to the health and well-being of human beings, the development of means of measuring its physical intensity and the discovery of methods and materials for sound absorption and sound insulation which make the reduction of noise possible.

The quantitative aspect of noise, together with the decibel scale on which noise levels are represented, can best be shown as in Table 1. By comparing

fighting the battle of production in shops and factories.

The following figures are taken from a recent paper by Hale J. Sabine and R. A. Wilson¹ giving the results of noise measurements in a number of war manufacturing plants (Table 2). These levels are of the same order of magnitude as those in boiler factories, sound intensities which otologists recognize as the cause of so-called "boilermakers' deafness."

There is a wealth of reliable data from medical sources in support of the statement that sustained exposure to noise is a "contributing factor in impaired hearing, chronic fatigue that lowers bodily resistance, neurasthenia,

TABLE 1

Noise Level (decibels)	Physical Intensity	Example
0	1	Threshold of hearing
10	10	Whisper at 5 feet
20	100	Very quiet room
30	1,000	Quiet private office
40	10,000	Subdued conversation
50	100,000	Business office
60	1,000,000	Ordinary conversation
70	10,000,000	Busy city traffic
80	100,000,000	Chicago elevated at street level
90	1,000,000,000	Pneumatic drill, 10 feet
100	10,000,000,000	Subway express passing local station
110	100,000,000,000	Airplane propeller noise
120	1,000,000,000,000	heard at 10 feet
130	10,000,000,000,000	Threshold of painful sound

these levels with the levels measured in manufacturing plants we can form some conception of the acoustical environment of the men and women who are

increased blood pressure, and decreased working and mental efficiency," and that "noise should rightfully be classified as an occupational hazard along with gases, fumes, dust, toxic liquids, and bacteria."

Bulletin 166, 1930, of the New York Department of Labor, states that of

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

Wood saw.....	100

1,040 workers in noisy industries tested for deafness, the highest percentage of hearing impairment for any age group was from the noisiest industries. Of the 246 persons in this group found to be deaf, 155 cases were traceable to industrial causes. In his work, *Occupational Disease*, W. G. Thompson² states that 45 per cent of locomotive crew men have impaired hearing. McCord³ gives 52 per cent as the incidence of deafness among train dispatchers, and this occurs largely in the telephone ear—the left. Recent studies on the effects of noise in military airplanes gives the noise level in the cabin of a two-engine bomber as 115 decibels. The measured loss of hearing, after 10 hours' exposure to this noise level, is in some cases as great as 30 decibels. Only after 36 hours following exposure do most of these cases show complete recovery. In a recent paper, "Acoustic Trauma in Man," Dr. H. B. Perlman⁴ states, "Many types of sound stimuli are now known to be injurious to the ear," and he lists among these the noises of pneumatically-driven tools, gasoline motors, Diesel engines, and locomotive whistles.

Occupational deafness is the most spectacular and widely recognized type of injury resulting from extreme noise. Less obvious but not less serious is the nervous fatigue which noise induces. Perlman⁴ points out that in the presence of intermittent noise there is a periodic tension and relaxation of the

involuntary musculature by which the fibers of the auditory nerves are protected from very loud sounds, just as the eye is protected from very intense light by the contraction of the pupil. The unconscious nervous strain produced is similar to that from a flickering light. Dr. Foster Kennedy⁵ found that a sharp loud report increased the intracranial pressure by as much as fourfold. He says: "Constant noise excites and irritates, it alters conduct, it causes loss of temper and plays a part in quarrels. To overcome the effect of noise, a strain is put on the nervous system leading to neurasthenic and psycasthenic states."

Smith and Laird⁶ found that in four healthy persons a decrease of 37 per cent in the number of stomach contractions results from exposure to sound levels of 80 to 90 db. Experiments on decerebrated dogs have shown that auditory stimulation produces reflex responses in the entire sympathetic nervous system. Laird⁷ reports that the metabolic rate of four typists working at maximum speed decreased from 71 per cent to 52 per cent over the rate when at rest, as a result of a 7 decibel drop in the noise level.

That the ill effects of noise are not consciously recognized does not alter the fact that they exist as a constant drain on nervous and physical energy. The amazing capacity of the human species for adaptation to any environment is perhaps the sole claim which we mortals have to first place in the evolutionary scheme. But adaptation to a bad environment does not do away with the resultant evils of such an environment. Nor does it reduce the social obligation to improve it.

One of the sure ways to get remedial action under a capitalistic economy is to establish the fact that such action will yield results that can be measured in dollars and cents. About twenty-five years ago, it was found that the

noise in business offices could be reduced by the application of sound absorbent treatment to the ceiling and walls of office spaces. That this reduction added to the comfort of office workers was obvious. Proof that it yielded returns in increased output of the office force has been given by numerous investigations by office management. One of the most convincing was that made by the Aetna Life Insurance Company, and reported by P. B. Griswold to the National Office Management Association in June, 1930. Employees in the departments studied worked on a bonus system, under which bonuses were awarded on the basis of the efficiency of each department as a whole. Records of efficiency in three departments were kept for a year prior to installing absorbent treatment, and for a year afterward, all other conditions remaining constant over the whole 2 year period. The reduction in the noise level was 8 decibels, approximately 50 per cent in the loudness. The measured increase in efficiency in these departments was 8.8 per cent, the decrease in the number of errors was 25 per cent.

While the purely commercial value of quieting for office workers has become a commonplace, yet it has been only within the last few years that any serious attention has been given to the problem of noise in industrial plants. Only with the war demand for increased production and the influx of women workers into heavy industries, has the noise problem received any consideration on the part of industrial management. Dr. Foster Kennedy⁵ cites the results of a study of Bogardus in 1911 to the effect that fatigue was a contributing cause in 82 per cent of 2,678 accidents examined. It is a well established fact that women are more subject to physical strain and have a greater short-sickness rate than men. If women are to retain (which God for-

bid) any considerable part in heavy industry then, from the standpoint of both public health and efficient management, the greater susceptibility of women to an adverse acoustical environment should be recognized.

The control of noise in industrial plants is a far more difficult problem than in business offices. Noiseless (or nearly so) typewriters, yes! But a noiseless punch press or riveter, no! The seven or eight decibels reduction to be had by absorbent treatment changes the annoyance of a noisy office to a condition of reasonable comfort. But the same reduction in the 90 or 100 decibels in a factory still leaves the din much above the comfort level. However, experience in a considerable number of recently constructed plants has shown that benefits beyond what might be expected from the mere reduction of noise level follow from acoustical treatment. Sabine and Wilson¹ state that their investigations led to the conclusion that "It is often possible for an acoustically treated area to be more comfortable than an untreated area having actually a lower noise level."

Analysis of the comments of workers in plants that had been acoustically treated disclosed that two elements, partly psychological and partly objective, contribute to the "noisiness" of a worker's environment.

The first is reverberation, that is the prolongation of a sound by repeated reflections from highly reflecting wall and ceiling surfaces. In a reverberant space, the worker has the sensation of working at a noisy machine in a noisy environment. Replacing the reflecting surfaces by absorbing surfaces reduces the environmental factor, thus markedly reducing the annoyance, even though the measured noise level is not greatly decreased. The second element is the so-called "spreading effect" of sound. In an open space the intensity of sound from a given source falls off rapidly as

the distance increases. In reverberant rooms the sound intensity from a single source is almost independent of the distance from the source—the sound spreads with little diminution with distance. As absorbent treatment greatly reduces this spreading effect, the man working at a noisy machine has the feeling of a relatively quiet surrounding. That workers recognize this effect is attested by their comments on conditions before and after acoustical treatment, such as, "The noise of that machine over there stays where it belongs," or "Before, it seemed like every machine in the plant was making noise. Now I can hear only the ones right around me." That absorbent treatment of factory walls and ceilings is worth while is evidenced by its increasing use in modern industrial plants.

Further reduction of factory noise can be obtained by intelligent planning of the plant layout. Isolation by means of effective shock mounting of heavy machines will reduce building vibrations which are transmitted with almost undiminished intensity throughout steel and concrete structures. Extremely noisy machines should be segregated from areas which would otherwise be relatively quiet. I recall one instance where the screech of a wood planer in one end of a packing room made a terrific racket for scores of girls and women who might otherwise have worked in relative quiet.

An illustration of this means of noise reduction is in the designing of airplane engine test cells. Before acceptance by the Army or Navy all engines must be subjected for many hours to extreme tests and measurements. The noise generated by a 1,500 to 2,000 horsepower internal combustion engine enclosed within concrete walls is something that would better be imagined than experienced. Levels of 130 decibels and more are created, corresponding to sound intensities 1,000 times that

in the proverbial boiler factory. Yet by properly designed walls, shock mounting of the engines under test, and providing tightly closing sound insulating doors of special construction, it has been possible to secure a degree of insulation that reduces the noise level in the adjacent test rooms to levels of the order of 80 to 85 decibels. Here the solution of the noise problem was an absolute necessity for the engineers making the tests.

In spite of all that can be done, however, it must be admitted that factories where steel mightily smites steel are bound to be noisy places. Recognizing the fact that noise is a health hazard, all possible measures to protect workers from its effects should be taken. Among these should be (1) the employment of men rather than women for jobs where noise is excessive; (2) allowance of frequent rest periods to relieve the strain of prolonged exposure to noise; (3) provision of simple ear defenders for those working at extremely noisy machines (the fifteen or twenty decibel reduction afforded by a plug of cotton moistened with vaseline may make the difference between injury and safety); and (4) recognition that work in extreme noise takes more out of the worker than the same amount of labor in quiet surroundings.

The problem of noise in low-cost multiple unit dwellings has received very little, if any, attention in this country. Even in apartment houses that are well above the low-cost level, the transmission of sound between adjacent apartments and between floors is all too frequently a just cause for serious complaint. Scientific measurements have shown that for the usual types of construction the insulation for airborne sound afforded by partition walls is almost wholly a matter of their weight. Light, cheaply built walls and floors are slight barriers to the passage of sound. Today, sound insulation can

be obtained only at a price, and this price is well above the limit set by rentals for low-cost dwellings.

However, cheap means of sound insulation are not impossible. It is only that no serious research on the problem has as yet been carried out. Only when we become fully alive to the fact that quiet living conditions are essential to the health and efficiency of the industrial worker, will the question of noise receive the attention it deserves in the planning of workers' homes. We note in the news that one million dwelling units will be needed to convert from wartime to peacetime housing. Only by insistent and coöperative effort on the part of architects, scientists, and building authorities have we any hope that these new homes will be any less noisy than the boxes stacked one on top of another in which millions of workers' families now have to live.

A part of the problem of industrial noise is relief from the endless clatter and racket of urban life. The most effective and sustained effort in this direction has been put forth in New York City. This began in 1929 with the appointment of a Noise Abatement Commission by the then Commissioner of Public Health, Dr. Shirley W. Wynne. The full story of the work of that commission is contained in a comprehensive brochure under the title of "City Noise," which has served as a textbook and guide for similar campaigns in other cities.

Since that time the flood of noise in this city has ebbed and flowed with the varying zeal of city authorities in the enforcement of the police restriction on needless noise. My personal judgment as a frequent visitor is that New York is a much quieter city now than it was fifteen years ago. We all know, though, that there is still a long way to go along this road. The experience, here and in other cities, shows that sporadic and hysterical "ballyhoos,"

with unenforced police regulations against noise are futile unless coöperation of the public at large can be obtained.

To meet the need for a sustained, consistent, nation-wide campaign of education for less noise, the National Noise Abatement Council was set up five years ago. This is an association of manufacturers, civic and business groups, and others, organized for the purpose of promoting a "national consciousness of the need for noise control; to publicize the causes and the cost of noise, and ways and means for controlling and abating objectionable noises on city streets, in factories, offices, schools and homes." From small beginnings, the movement has spread and today there are in 48 of the larger cities of the country committees actively at work in carrying out the purposes of the Council. On every hand there is evidence of a growing interest in noise abatement. With the financial backing of commercial interests, the work of the Council promises to be a sane and persisting campaign for relief from an evil which all public-minded people recognize as a menace to the health and sanity of us all. Noise, once created, travels at a speed of one-fifth of a mile per second in ever-widening circles, and nothing can be done about *that*. The only effective remedy is to get people to make less of it. To get this idea across to the public at large is the goal of the National Noise Abatement Council. The coördination of the activities of the Council with those of groups attacking the problem from the standpoint of industrial hygiene should materially help in extending the zone of quiet into the whole industrial environment.

Conference on Rheumatic Fever

A conference on rheumatic fever under the auspices of the American Heart Association was held in New York, N. Y., on January 26 and 27 to appraise the rising tide of professional and lay interest in rheumatic fever as a public health problem and to consider what can and should be done. The American Public Health Association was represented at the conference by David Rutstein, M.D., Deputy Commissioner, New York City Department of Health, and Reginald M. Atwater, M.D., Executive Secretary of the A.P.H.A.

The conference adopted the following resolutions:

1. Because of the magnitude and importance of the rheumatic fever problem, this conference is strongly in favor of the extension of public programs, supported by federal, state, and local funds, for the study, prevention, and treatment of this disease. Moreover, we believe it is essential that additional funds be secured from private sources for the purpose of special studies to increase basic knowledge of the disease, for professional education, and for increasing public awareness of the problem.

2. In order to accomplish the purposes mentioned above, this conference recommends that a Council on Rheumatic Fever be formed under the leadership of the American Heart Association, and that this council shall include representatives of interested organizations.

Subsequently the American Heart Association accepted responsibility for the formation of a Council on Rheumatic Fever and has invited the American Public Health Association, along with other agencies, to participate in the formation and work of this council through the appointment of suitable representatives. It is anticipated that the council will be an active body with its own offices, a full-time director, and a competent staff of secretaries and assistants.

The functions of the council are expected to include the formulation of adequate programs for communities of various sizes, advice to governmental, professional, and lay groups interested in the disease, and the sponsoring of research in many aspects of rheumatic fever.

The Physician's Confidential Medical Report of Cause of Death*

THOMAS J. DUFFIELD, F.A.P.H.A.

*Registrar of Records, Director, Bureau of Records and Statistics,
Department of Health, New York, N. Y.*

EVERY sound public health program must be soundly based. Preferably that basis should be complete statistics of morbidity. No state or city in the United States, nor in any other country so far as I know, has yet attempted to adjust its public health program to this basis. Rather, communities have generally been content to develop public health programs on the basis of the reported causes of death and the reports of cases of a limited number of diseases, which are generally classified under the term "preventable."

Mortality statistics are a poor substitute for morbidity statistics as the basis of public health planning and administration. In a city like New York, for example, the discharge diagnosis for every person admitted to the municipal hospitals would probably be a much sounder basis for the public health program than the combination of statistics of mortality and preventable disease presently used. However, until the basis is changed, everything possible must be done to make our present guides as accurate as they can be. At this time, when so many of the physicians who normally practise in New York City are in the military services and those remaining in civilian practice are so hard pressed, there are many indications that the reporting of cases of

illness—tuberculosis and pneumonia, to cite two important examples—is grossly incomplete. It is, therefore, of the utmost importance that the cause-of-death statistics be of the highest order.

In New York City, we are attempting to overcome the shortcomings of the traditional methods of reporting deaths and their causes by experimenting with a form of reporting deaths from natural causes in a manner which assures that the medical diagnosis will be treated as a confidential communication to the Department of Health. It is my purpose in this paper to outline briefly the legal bases for this procedure and the practical reasons which, we feel, make its adoption essential.

PERTINENT LEGISLATION

The Civil Practice Act of the State of New York provides that a physician ". . . shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity . . ." other than in the case of a crime committed upon a patient under 16 years of age,¹ except when, upon a trial or examination in open court, the prohibition cited above is expressly waived by the patient or by the personal representatives of a deceased patient.² Obviously, the statement of the cause of death of a person in a death certificate does not fall among the exceptions to the application of these laws.

However, the New York City Charter gives to the Board of Health of

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

the City, the power to adopt a Sanitary Code which "shall have the force and effect of law,"³ and the Charter expressly instructs the Board of Health to prescribe the persons who shall be required to file certificates of death with the department and the form of such certificates.⁴ Moreover, the Administrative Code of the City authorizes the Board of Health to issue transcripts of death certificates and to determine the form of such transcripts.⁵

In accordance with these general and specific powers granted by the Charter, the Board of Health, on December 12, 1938, adopted a revision of Section 33 of the Sanitary Code perpetuating regulations requiring the reporting of deaths that have been in effect for 150 years, and providing, when deaths were due to natural causes, for the reporting of the medical diagnosis of the cause of death on a confidential medical report.

COURT RULINGS

The provisions of Section 354 of the Civil Practice Act and of Section 33 of the Sanitary Code of the City of New York would appear to be in conflict and, in fact, they are. But the Court of Appeals of the State of New York has ruled that in spite of the provision of the Civil Practice Act which apparently prohibits a physician from disclosing information regarding the illnesses suffered by a person, since deceased, it is a proper exercise of the police power granted to municipalities to require the reporting of deaths, and the causes thereof, because such information is required for *public* purposes, namely, the protection of the public health.⁶

Hence there may be no question regarding the authority of the Department of Health of the City of New York (a) to require the reporting of deaths and the causes thereof, (b) to prescribe the form and manner of reporting, (c) to issue transcripts of death certificates,

and (d) to prescribe the form of such transcripts.

The highest courts of the state have apparently not passed on the propriety of the issuance of transcripts of death certificates including the cause of death as reported to it by a physician in attendance upon a patient before his death, by a department of health, because that right has not been challenged by the medical profession. But the Court of Appeals of the State of New York has ruled that a certificate of death or a certified copy thereof is not admissible in any court action between private parties, as proof of the cause of death,⁶ although it has been held that such a document may be received as *prima facie* evidence of the fact of death. Hence exclusion of the cause of death from the certificate of death does not deprive persons receiving copies of essential information.⁷

PRACTITIONER'S PRACTICES

It is well known to some of us that physicians as a group will not invariably report the true cause of death on a form which will be reproduced photographically, or otherwise, and released to anyone—particularly to a relative of the decedent—for use in proving the *fact* of death of the individual in the settlement of his estate. Such a disclosure would not only violate the provisions of law mentioned above but it would also violate one of the principles of medical ethics summarized in the following quotation from the oath of Hippocrates:

"Whatsoever house I enter, there will I go for the benefit of the sick. . . . Whatsoever things I see or hear concerning the life of men, in my attendance on the sick or even apart therefrom, which ought not to be noised abroad, I will keep silence thereon, counting such things to be as sacred secrets."

Even if physicians were not guided

by any such principle of professional ethics or were not prohibited by law from disclosing information they collect either through inquiry or examination in the course of treating patients, they would generally refrain from divulging such information, particularly if it should reflect unfavorably on the patient, because of the fear that the patient or his relatives might take offense and that he might in that way lose clients. Under such conditions, the Department of Health may be deprived of important and essential information.

A CONFIDENTIAL METHOD OF REPORTING CAUSES OF DEATH

Recognizing the principles cited above, a new method of reporting deaths due to natural causes has been devised and used in the Borough of Manhattan, City of New York, since January 1, 1939. The Sanitary Code covers this matter in the following terms: "The physician's confidential medical report of a death, required to be filed with such certificate of death, shall be deemed not a part of the certificate of death and shall be regarded and treated as a confidential and privileged communication, and shall not be subject to subpoena or open to inspection for any purpose whatsoever, except for scientific purposes approved by the Board of Health."

This confidential medical report, which is separate and apart from the certificate of death, is forwarded to the department in an envelope sealed by the physician. In practice, the funeral director acts as messenger and the death certificate and the confidential medical report are filed with the department at the same time. It is obvious that the confidential medical report must be filed before any burial permit can be issued.

It is to be noted that deaths when unattended by a physician, deaths that occur under unusual or suspicious conditions, as well as deaths from external

cause—accidents, homicides, and suicides—are required by law to be investigated by the Office of the Chief Medical Examiner of the city and that such deaths are reported on the form of certificate in which the diagnoses are fully given. The public official who prepares such a certificate is in an entirely different category from that of the physician who attended a person during his lifetime. The law provides that, except in cases under investigation by a Grand Jury or a District Attorney, the records of the Office of the Chief Medical Examiner shall be open to inspection.

Those persons who developed the idea of having a health department issue complete copies of death certificates, including the medical diagnoses recorded by the attending physician, did not realize, I am sure, that the issuance of transcripts of death certificates might lead to a situation under which a health department would be deprived of important information—the information, in fact, that constituted the primary reason for having death registration a function of a health department.

Under the usual practices of reporting deaths and issuing transcripts, diagnoses that cause trouble between physicians and the relatives of deceased persons fall into four categories:

1. Those that tend to disgrace the memory of the deceased: congenital malformation, mental deficiency, syphilis, alcoholism, suicide, epilepsy.

2. Those that cause fear: diabetes, tuberculosis, cancer, heart disease, poliomyelitis, leprosy, smallpox.

3. Those that might reflect unfavorably upon the physician: birth injury, puerperal septicemia, infantile diarrhea, induced abortion.

4. Those that might cause difficulty in collecting insurance. (There are still some companies that disclaim all liability in the event of death from tuberculosis.) In other instances, the combination of the reported cause of death and the duration of the disease may clearly imply that a policy of insurance was obtained by fraud. I have

no knowledge of the number of instances in which controversies arise between insurance companies and the beneficiaries of life insurance policies, but I do know that they occur. If an insurance claim is contested, the person named as beneficiary in an insurance policy blames the physician, justly or unjustly, and the physician loses that person and his or her family as clients. Physicians are human, and the pressure to withhold information is great. However, any deviation from the truth tends to vitiate the statistics of death by cause and thus deprive the health department of information that is essential to the planning and administration of the public health program.

CONCLUSION

It was never contemplated—by the author, at least—that the use of this confidential method of reporting causes of death would correct all the shortcomings of cause-of-death reporting overnight. It required twenty years to achieve the desired results in Switzerland, where this method of reporting

was first applied, and it will evidently require years here. A test is now being made to determine whether this method is presently yielding results that are superior to the old method of open reporting. Unfortunately, the results of this test are not yet available. One thing can be said: physicians apparently like it. When asked if they would object to extension of this form of reporting to the remainder of the city, the Medical Societies in the other four counties all voted in favor of it.

7. Actions have been threatened, and at least one proceeded so far as to be placed on the court calendar, to compel the department by mandamus to issue a copy of the confidential medical report. These actions have invariably been withdrawn before trial.

Rôle of the Public Health Laboratory in Gas Defense*

EUGENE W. SCOTT, PH.D.

Chief Gas Officer, Office of Civilian Defense, Washington, D. C.

IT seems natural to introduce this subject with a brief discussion of the likelihood of gas attacks on civilians in this country or in Europe. Various military authorities have expressed personal opinions that Germany would resort to the use of war gases when she felt that there was something to be gained by their use. The manner in which the German "blitz" operated in the days when it was the dominant military force in the first part of the war precluded the effective use of war gases. There was no need of them and in many cases the use of persistent war gases would have resulted in slowing down the advancing armies. Now, there is another reason deterring Germany from introducing chemical warfare; that is, the knowledge that both England and the United States have plentiful stocks of chemical warfare agents, and that they are in a position to retaliate in full measure for anything which Germany may use. It seems entirely possible therefore that chemical warfare will not be initiated in the European theater of operations.

On the other hand, Japan, with its home bases relatively secure, may at any time introduce gas warfare. There is no question but that the advance army commands and the naval facilities of the Japanese fleet are equipped with gas munitions which the com-

mander may decide to use with or without official approval of higher authority. It seems certain that Japan will not hesitate to use war gases because of humanitarian reasons.

Since December, 1941, the Office of Civilian Defense has advocated and aided in the establishment of civilian defense organizations for all cities in the United States. The establishment of complete organizations has been emphasized particularly in the coastal regions and areas bordering on the Great Lakes and Gulf Coast. Gas defense was started with the Decontamination Units which were organized at the same time as the Air Raid Warden, Auxiliary Police, Auxiliary Fire, and related units. Later, the gas defense organization was expanded to include individuals with duties specifically related to identification and protection against war gases. In many places this organization has been trained and is in a state of readiness. It should be noted that the recommended gas defense organization is considered only a basic nucleus which will be expanded if gas attacks become a reality.

Some individuals believe that no form of civilian defense will be required in this country, since they think that the Germans will have their hands full defending their own country and conquered areas. It is also felt that Japan, with the loss of its bases in the Aleutians, is not capable of attacking the continental United States. This feeling of complacency is the most im-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

portant thing we have to combat at the present time. Unquestionably it has become more difficult for either of these enemies to reach this country by air. It is still not impossible for them to do so. The Office of Civilian Defense, therefore, is obligated to maintain the civilian protection organization which has been established until it is certain that there will be no need for it.

The gas defense organization established by the Office of Civilian Defense for the United States comprises in the neighborhood of 10,000 volunteer workers. We expect to keep these persons enrolled for the duration of the war or until we are absolutely certain that gas will not be used on civilians in this country. This gas defense organization is made up principally of the chemically trained men of the communities and, in case of gas attacks, will form a large nucleus for the expansion of gas protection services as required.

The Office of Civilian Defense is an advisory organization to the states and consists of a staff in Washington and field staffs in nine regional offices throughout the country. At each location there are one or two individuals responsible for the organization of the gas defense program. It has been recommended that each state appoint a State Gas Consultant to be responsible for the gas defense program of the state, and most of the states have done so. Finally, it is expected that each large city will appoint a Senior Gas Officer to direct the gas defense program of the community. Under him will be found the identification officers of the Gas Reconnaissance Unit. He should also be responsible for the training of the Decontamination Unit and the direction of the unit if the need arises. In addition, all hospitals and casualty stations in the critical zones have been advised to select facilities which may be used for the cleansing of injured persons who have become contaminated with vesicant

war gases. Finally, we have the Emergency Medical Service as a part of the gas defense organization, in that any physician in the service may be called upon to treat injuries due to war gases. In order to provide these doctors with the knowledge required to treat such injuries, a training program on the treatment of chemical casualties has been carried on by the medical schools of the country in coöperation with the Office of Civilian Defense.

In addition to the direct protection of persons from these agents, it is also important that their food and water be protected. In case of a gas attack, considerable contamination of both food and water may occur. The contamination of large supplies of water such as city reservoirs is not very likely, since enormous amounts of war gases would be required to make the water unsafe to drink. This is particularly true if the stored water is subjected to a purification process from which it is pumped directly into the water supply system. Purification processes such as chlorination, coagulation, sedimentation, and filtration will ordinarily remove almost any war gas contaminant, although there are a few exceptions. Contamination can be detected quickly by marked changes in the pH of the water, in the chlorine demand, and in the chloride content of the water. The purity of a public water supply is the responsibility of the city department regulating the water supply, but in most cases the health department must ascertain by analysis whether or not such water is safe to drink. In times of emergency, these responsibilities are not changed, but routine purification and analyses are not sufficient. Special precautions must be taken to insure that the enemy attacks have not disturbed the safety of the drinking water. If war gases have been used, special tests for such materials should be inaugurated to insure that contamination will be detected as

soon as it occurs. The tests mentioned above are not specific, but are easy to perform and are good indications of contamination. In contrast to public water supplies, private water supplies might easily be contaminated during war gas attacks from the air and any such supplies in a gassed area should be sampled and analyzed by the health department as soon as possible after such attacks.

The chief duty of the health department of any city is to protect the health of the community under enemy attack as well as in peacetime. In the case of an enemy attack, the problem becomes more difficult, even if only explosive bombs are used, and still more difficult if these bombs are mixed with war gases. All sources of food and all food supplies in an area contaminated by war gases must be examined, therefore, before such sources or such foods are permitted to be used. This is the chief problem which will confront the health department in case war gases are used.

It will not be the responsibility of the Senior Gas Officer of the community to certify that food and water are or are not contaminated. However, he will indicate to the health department laboratory what areas have been contaminated and his organization will aid in the collection of food samples for analysis and in carrying out the orders of the health department. In many cases it may be advisable to utilize the services of the Gas Reconnaissance Unit in the inspection of suspected foods, since a widespread area of contamination would require the work of a considerable number of individuals in order to carry out such inspections. In most cases, the staff of the Senior Gas Officer is composed of individuals experienced in chemistry with special training in chemical warfare. With rather brief instruction it should be possible to utilize them very satisfactorily in carrying out this necessary

work of inspecting suspected foods.

The public health laboratory should therefore be prepared to analyze food, milk, and water for war gases. All the common war gases can be detected specifically by means of reactions which are described in the literature and in standard reference books on the subject of war gases. Two books of particular value are Jacobs' *War Gases, Their Decontamination and Identification*, and Sartori's *The War Gases*. Memorandums on the detection of war gases in water have been prepared and can be obtained from the Stream Pollution Investigations Station of the U. S. Public Health Service at Cincinnati, Ohio. In addition to these sources the Office of Civilian Defense has recently published a memorandum on "Identification of Chemical Warfare Agents" which will be available from the Government Printing Office. The samples can be analyzed qualitatively by aspirating air from the sample bottle or flask over sensitized paper, or through silica gel or an absorbing solution. The absorbent solution or gel can then be tested for the agent. Most of the chemical reactions used in the identification of chemical warfare agents can be very satisfactorily performed on silica gel without eluting the absorbed gas.

Many public health laboratories have sent members of their organizations to gas specialist courses given under the auspices of the Office of Civilian Defense at War Department civilian protection schools and at state gas specialist schools. These men have been given sufficient training to carry out any necessary analyses. In some states this gas specialist training is still being carried on, and any member of a public health laboratory who so desires can obtain some training under this state training program. Almost every large city of this country has appointed a Senior Gas Officer, and he has received training at one of these sources.

If the public health laboratory desires assistance in training its men, he will invariably be eager to coöperate with them in seeing that such training is provided.

To summarize briefly let me say that the *Office of Civilian Defense* and the

civilian defense organizations of the local communities are relying upon the health departments to coöperate in the overall gas defense program by providing protection of the food and water supplies in case of emergencies caused by gas attacks.

THE EDITOR RESIGNS

DR. HARRY STOLL MUSTARD has resigned as Editor of the JOURNAL. The Editorial Board makes this announcement with profound regret and with the free admission that the resignation, offered some months ago, was accepted only after it was abundantly clear that no argument or persuasion could prevail upon him to change his mind.

The Board believes it speaks for the JOURNAL's 10,000 readers when it expresses gratitude for the good fortune which retained Dr. Mustard's interest for as long as three years and two months. He is a busy man, a much sought-after man. Competition for his attention is always keen and never more so than in these war years. There must have been many occasions when matters of great weight and urgency wholly absorbed him, cruelly consuming mental and physical energy. A lesser person would have found intolerable the sustained demands of a monthly magazine and promptly sloughed them off. We know he has had long absences from the country, preceded and followed by close-packed weeks of attention to continuing commitments. The JOURNAL was only one of many. Yet every editorial, save two, which has appeared from January, 1941, through February, 1943, has come from his pen. Their thoughtfulness, their exact scientific focus, their penetration, their climactic punch-lines give evidence in every finished period of the painstaking care with which they were prepared. Time went into them, with time at a premium, and there was always a dead-line, and the writing of two and sometimes three editorials a month was by no means all the Editorship entailed. Dr. Mustard himself did nothing by proxy and he held others to the same punctilious ideal. One of his first official acts as Editor was to set down, in unequivocal terms, his convictions about book reviewing. "Books accepted for review by a person should be reviewed by that person," he wrote, "and not by an associate. If the reviewer finds that he cannot himself undertake the task, he should return the book to the editorial office." In that same letter occurs the famous line that many a recipient has chuckled over—"Reviewers should avoid cliches, jargon and ostentatious polysyllabics." It is a rule which scrupulously governs his own writing. He read every book review and graded it, to remind

himself later of the competence of the reviewer. He was conscientious in acknowledging and commenting upon manuscripts offered for his opinion. In short, he worked at the job, and somehow extended his days and himself to encompass it, and to do it superbly, as he has done with all the other things dependent upon him for guidance, direction, and completion.

But Dr. Mustard does not use press of work as a reason for giving up the Editorship. The idea would not cross his mind that he is more beset than the next man. His resignation is the application of a principle in which he deeply believes—that those who have enjoyed the spotlight for a time must make way for the young, the eager, the courageous, who are crowding the wings waiting their turn on the stage. He was entirely serious when he publicly proclaimed in the September JOURNAL:

“The Editor has a feeling that old names and old faces, including his own, have too long occupied strategic positions on boards and committees. . . . If someone wants to campaign for a candidate under forty for the Governing Council, the Executive Board, or Editorship of the JOURNAL, we shall joyously back his man (unless he has served a prison term of more than a year) against the fifty-and-over field.”

Lest there be misunderstanding, it is important to state at this point that Dr. Mustard was born in 1888.

In telling each other what constitutes a good editor, as they have reviewed qualifications of possible candidates to succeed him, the members of the Editorial Board have been finding out what constitutes Harry Mustard. Instantaneous presence of mind is one of the ingredients—of a kind that picks up a remark on adolescents, for example, at a meeting, pays a pretty compliment to the speaker and turns the episode into grist for the editorial mill. The ability to recognize a stuffy idea a mile away and take a fall out of its proponent with finality and without offense, is another. Still another is the capacity to reflect upon observations and experiences, some of them dull enough in the acquiring, no doubt, and to relate them brilliantly to a present situation. Versatility is a *sine qua non* in an Editor of a magazine covering as broad a field as public health. Mark the range of Dr. Mustard's subjects and note how completely at ease he is in each; he has discovered their “essences” in George Santayana's use of the word.

No, the qualities that Dr. Mustard possesses and that make a good Editor for the JOURNAL are rarely associated with the young. Granted that one or another of his young people could bring to it his writing skill, what time or opportunity has such a person had to synthesize a philosophy from memories and experiences?

The Editorial Board is unanimous in its feeling that age is not a criterion to be unduly emphasized in the selection of an editor, but that what it must search for is someone having the vigor and fearlessness of youth, the experience and judgment of age, and the ageless genius for expression which the retiring editor possesses.

ORGANIZED LABOR, A NEW ALLY FOR PUBLIC HEALTH

MANY a community organizer has wished that organized labor would rally to the support of his cause with some spontaneity. If he has tried to bring in the unions he has probably experienced a more or less polite brush-off. Employee health has been a sore spot with the unions ever since management became

insistent about it and tried to use these methods as means to get rid of workers it did not like. For a long time health has been identified with coercion and repression from above. It has seldom had the benefit of wholehearted coöperation from labor itself because the workers themselves wanted health.

The tide appears now to have turned. Perhaps as a result of wider understanding by the public of the aims of health, or perhaps as a result of the organization by the great unions of committees concerned with the National War Fund, there has arisen from labor itself an organized desire to share actively in health promotion and to bring to the worker himself the obvious benefits of good health. A recent conference at the invitation of the American Public Health Association between the staffs of the CIO and of the A F of L committees on the National War Fund and the executives of national health agencies has pointed up this new attitude. No longer is labor being coerced in this area. Labor is aggressively seeking means of writing intelligent health clauses into its contracts and is trying actively to coöperate in the planning and operation of community health services. Very likely the influence of the central labor bodies will soon be felt in local union circles. It is a new movement with tremendous potentials.

Recent attention has been drawn to the action of the California State Federation of Labor where examinations for syphilis have been endorsed and recommended to local unions. In this case the initiative came from a voluntary group, the California Social Hygiene Association, which found a responsive and intelligent labor leadership. From this beginning has come a request from labor itself for the inclusion of routine chest x-rays for the protection of the worker and his associates. This represents a fresh aspect of the search for unrecognized tuberculosis and one that will be welcome to those whose business it is to advocate these examinations. It would not be surprising for this demand to spread from union to union until it may tax the ability of the official and the voluntary agencies to supply service. It may forecast a useful peacetime disposition of the x-ray equipment now so widely used by the military forces. It suggests also a fruitful direction in which the unprecedented income from the Christmas Seal Sale may be used. Of course, such case finding is only the first step and the resulting demands for service from nursing and other staffs will not make simpler the present difficult job of the administrator. Even so, it may be the opening door to significant achievements, including practical use of the routine physical examination. What if the demand for this procedure should now come strongly from the people themselves?

All the foregoing gives point to the volume recently published under the auspices of the National Tuberculosis Association on labor relations. The time has come to do away with the amateurish activity which has been typical of health workers in the past and to make our contacts with the unions and with management in conformity with approved methods. This manual, under the title of "Tuberculosis: Labor and Management" is prepared for the workers engaged in local tuberculosis service who need a quick bird's-eye view of present industrial relations. Although focused on tuberculosis, it opens up in a practical way the matter of industrial relations, and can profitably be read by all public health workers, both official and voluntary.

"This brief manual is not a cook book. It contains no fool-proof recipes furnishing the final answer to all problems of human relations arising from the impact of a complex disease, tuberculosis, upon a complex structure, modern industry. Let it be said, once and for all, there is no royal road, no easy short

cut, which will relieve man from the often unpleasant task of thinking things through."

The leadership which the National Tuberculosis Association has shown in this field of industrial hygiene is indeed commendable. The success of this initial monograph in the series planned by the Association will make its readers receptive to the subsequent manuals on Mass Radiography in Industry and on Viewpoints of Management and Labor as they appear.

Credit Lines

SO many requests have come to the Association for the address which Professor C.-E. A. Winslow of Yale University presented at the luncheon session held at the Annual Meeting of the American Public Health Association in New York, October 14, 1943, that it is reprinted herewith.

Greeting to Latin American Guests at the A.P.H.A. Meeting.

It is a very great pleasure to welcome the representatives of our sister republics to the south. Many of them have been our guests before, and have become dear and valued friends. Never before, however, have we had the advantage of such a galaxy of knowledge and vision in the field of public health. We look forward to a very great stimulus of our common activity in this country through what we shall learn from our distinguished visitors.

There are many ties that bind us together. North of the Rio Grande we recall what Washington and Lincoln have done in the timeless war against tyranny; but we are equally proud of the great liberators of the south, of Bolivar and Sucre, San Martin and O'Higgins. We may boast of Theobald Smith and Walter Reed; but we share your admiration for Oswaldo Cruz, for Chagas, for Finlay and Carrion. Cuba and the United States together fought yellow fever at Havana. Gorgas triumphed at Panama; and the recent triumphs of Barreto in Brazil in his victory over the gambiae mosquito have been glorious enough to justify pride in both hemispheres.

In the newer social fields of public health we in the United States can hardly claim to be comrades, but rather

followers. Certain of your Latin American countries pioneered in the enforcement of the eight hour day, and in the provision of other forms of labor legislation long before we followed in the north. The social security system of Chile is a model for the world; and we look with admiration at such enterprises as the rural school health centers in Mexico.

It is a common thing for a representative of one nation to attempt to compliment another by an emphasis on their likeness. It is not, however, a real compliment to say "We feel you are just like one of us." The essence of true internationalism is not a sea of uniformity but a complementing by various peculiar national characteristics of a whole that is more than the sum of its parts. Aquinas said that "Beauty is unity in variety"; and this is the real keynote of international relations.

You have many things we do not have, many peculiar and special contributions to the stream of world civilization. For example, the culture of many Latin American countries represents our only link with the ancient civilizations of these continents before the coming of Columbus, a link with the great primitive people who developed the Maya calendar long before the Gregorian calendar was in existence, and with the Incas of Peru who planned and executed an extraordinary program of national social security.

Then too you bring into the comity of nations those traditions and those qualities which made the period of the Conquistadores so glorious. In 1620 my ancestors were huddled in primitive wooden huts on the shores of Plymouth, but nearly a hundred years before (in

1532) the first printing press on this continent had been set up in México. My own university (Yale) is the third oldest in the United States, being founded in 1702; but a century and a half before this (in 1551) Mexico City and Lima had established their own great universities.

To the genius of Latin America we owe Orozco and Rivera, who stand in the very forefront of the world of art; Dario of Nicaragua in poetry, Rodo, the essayist of Uruguay, and Marti, the great philosopher of Cuba.

We think of ourselves in the United States as individualists, but the culture of Latin America has given a deeper and richer interpretation to the development of individual character and personality and to the evolution of all those qualities which make for the graciousness of life.

We face today the most critical challenge that has ever confronted the human race. The close of this war will demand almost superhuman efforts if our world is not to sink into the darkness of chaos. The hope is that by each free nation making its special contribution, displaying its special genius, all these contributions may be welded together into a great common effort to the end of the building of a world nearer to the heart's desire than any that has yet been known.

THE CARE OF COMMUNICABLE DISEASES IN GENERAL HOSPITALS

James E. Perkins, M.D., Director of the Division of Communicable Disease Control in the New York State Department of Health, Albany, has recently summarized the attitude of his department on the care of communicable diseases in general hospitals. The following is quoted from the January 17 issue of *Health News*:

In the early part of this century, there was a tendency on the part of municipalities to

build special hospitals for the isolation of communicable diseases. These so-called "pest houses" were designed particularly for the care of smallpox cases but were intended for the isolation of other acute infectious diseases as well. At that time, it was thought feasible to control communicable diseases in communities through isolation of recognized cases since it was felt that if all patients were isolated until they were no longer infectious, the spread of these diseases would cease. However, upon further investigation from a bacteriological standpoint, it was learned that in many communicable diseases, symptomless carriers and atypical cases which ordinarily would not be recognized as infectious are frequently more important in the spread of the disease in the community than the typical cases which can be detected. The routine hospitalization of acute communicable diseases for the sole purpose of limiting spread of the infection in the community, therefore, obviously would not accomplish this objective.

At present, hospitalization of contagious diseases ordinarily is recommended only in those cases requiring care from the standpoint of the welfare of the patient himself and which can be given only in a hospital and not at home. In rare circumstances, it may still be necessary to hospitalize patients from the standpoint of the protection of the community as, for example, in the case of a communicable disease discovered in a transient or occurring in a home in which for certain reasons proper isolation is impossible.

Concomitant with the development of our bacteriological knowledge of communicable diseases, techniques have been devised to permit the safe isolation of cases of communicable diseases in general hospitals. These procedures vary with the disease: some patients can be cared for without danger on a ward; others must be confined to a private room. However, there is essentially no communicable disease which can not be cared for safely in a private room on a floor on which there are other patients with noncommunicable diseases, providing certain techniques are practiced rigidly by the attendants. It has become increasingly clear that the training and skill of the attendants are much more important in controlling the spread of infection than the physical equipment provided.

In the opinion of the New York State Department of Health, therefore, separate buildings for the sole care of communicable diseases are not essential. In larger municipalities it may be more convenient for a hospital to have a separate building for this purpose, but this is a matter of convenience

and not necessity. In smaller places in which such a building would be vacant a large part of the time, an unnecessary expense to the community would be entailed.

Every hospital is dealing with communicable diseases whether or not it recognizes that fact. Because of the prevalence of carriers and atypical cases among the general population, it is inevitable that such carriers and cases will be admitted from time to time to a hospital even though the infection is not detected at the time of admission. The routine procedures followed in these hospitals, therefore, with regard to the hygienic practices of the attendants, the handling of food and dishes, and the use of various types of equipment (such as thermometers, enema apparatus, etc.) should be such that there is no likelihood of the transfer of secretions or excretions from one patient to another. If such techniques are not followed, sooner or later an outbreak is bound to occur through the introduction of pathogenic microorganisms by a carrier or atypical case.

FOOD HANDLERS SCHOOLS

The Food Division of the Memphis and Shelby County Health Department, Memphis, Tenn., organized a Food Handlers School which ran for 8 days recently under the joint sponsorship of the Memphis Restaurant Association and the Health Committee of the Memphis Chamber of Commerce. The School was conducted by personnel from the U. S. Public Health Service, assisted by the local city and county health department.

According to Marvin F. Carter, the Director of Health Education in the Memphis and Shelby County Health Department, the 12 sessions, representing 3 lessons, brought out a total attendance of 4,433 persons, representing fully 25 per cent of all food handlers in Memphis. According to Mr. Carter, there was excellent coöperation from the Restaurant Association, the Chamber of Commerce, the newspapers, and radio stations. Classes consisted of talks, demonstrations, motion pictures on bacteriology, food poisoning, communicable diseases, proper washing of dishes and glassware, and other means such as

single service containers to take care of rush hours when it is difficult to get dishes and glassware properly washed. Coöperating on the faculty were Major Male, Dr. Butterworth, and H. C. Taylor from the New Orleans office of the U. S. Public Health Service.

A certificate testifying to the attendance from a restaurant was issued by the county and city health department when more than 75 per cent of the food handling staff completed the course. In addition, small cards certifying to an individual's attendance were distributed. The percentage of persons in attendance marks this as a unique project. According to Homer N. Calver of the Public Health Committee of the Cup and Container Institute, similar schools are planned and under way in a number of cities.

RELATIONSHIP BETWEEN THE MEDICAL PROFESSION AND GOVERNMENT

In an address before the Westchester County Medical Society, White Plains, N. Y., January 18, 1944, Dr. Edward S. Rogers, Assistant Commissioner for Medical Administration, Bureau of Pneumonia Control, New York State Department of Health, Albany, N. Y., expressed a philosophy with regard to the practising physician, society, and government, which is worth pondering. This section of his address is printed by permission of the *Bulletin* of the Westchester County Medical Society. The full text is carried in the *Bulletin* for February.

I should like to start with two premises upon which, it seems to me, there can be no disagreement: First, that we, as a profession, are committed to the cause of progress, progress in the science of medicine and in the problem of its application to society. Second, that we are equally committed to a program of realistic growth in the belief that the two extremes, that of reactionism born of fear of change and of revolution born of avarice, are costly and undesirable in comparison to rational, well conceived and soundly guided growth by evolution.

If you will measure the present times by these standards, I believe you will agree with me that the fact of progress is inevitable, but that the method of progress is still a matter of choice. I am firmly of the conviction that regimentation is unnecessary and equally convinced that reactionism is pure folly because it cannot and should not overcome the stronger current of social growth, but by deviating attention from the realistic approach will only serve to leave the stronger current without effective control.

At this point, therefore, I should like to add a third premise—namely, that since progress and change in the application of medical care to society are not only inevitable but also desirable, this fact should be recognized by the profession. To this end, the medical profession should select or create, and give its support to, a class of physicians who are competent to devise and guide such growth. I further believe that it is a specialty in its own right, demanding men of particular qualification and background and that the specialty may well be called administrative medicine.

Do not confuse this with leadership. Medical leadership is the prerogative of no group or specialty, but belongs to those who rise in any branch of the profession to deserve it; but leadership is not synonymous with administration and organization in a functional sense; and these are what I am talking about.

Administrative medicine, in the sense that I am using the term, embraces several broad areas of activity. The medical administrator's first responsibility is the facilitation of the application of medical science to society. To do this, he must have a broad enough acquaintance with medical science to evaluate what is good and what is not, and to whom, to turn for technical advice; and he must also have a broad enough knowledge of society to know what its problems are and to know the good from the bad in the manner of answering these problems.

He must be able to recognize the interests of the medical profession, not only in serving society, but also in self-preservation—an honorable prerogative of any worthy group. And he must also be able to understand and evaluate the interests of society. Where these interests coincide, he should bring them together. Where they are in apparent conflict, he should reconcile them. Where they are in absolute conflict, he should guide them through periods of adjustment on both sides, avoiding injustices, and above all having wit enough not to destroy the basic rights of any group.

What good, for example would come out

of the regulation of medicine under some superimposed and theoretical system if, by so doing, the profession were to be made unattractive to men of the best professional calibre? Rather better, it seems to me, would be the process of enabling the medical profession to regulate itself within the broad concepts of our social growth.

The medical administrator must therefore know his profession and the leaders in it, if he is to serve it well.

As I have said, responsibility in leadership should not be confused with responsibility for operation. Our Congress and the President may be said to be in positions of leadership with respect to the war, but they do not, or should not, presume to direct the technical phases of our prosecution of the war. They should leave that to those who are equipped and in the position for such direct responsibility.

Similarly, I believe that medicine, through the voice of its organized bodies and outstanding leaders, should determine or pass upon the broad objectives of its growth, but the technical, complex and delicate task of actually directing such growth is not a part-time task for an untrained man. Nor does the structure of organized medicine provide the complete machinery for such administration.

Let us take a look at government, not perhaps as we may see it now, but rather as it should be. It seems to me that government should be the agency of the people whereby they provide themselves with the machinery for self-regulation in the best interests of all. The pressure groups that menace us today should have no power to go beyond making their just views and needs known.

If we will accept this definition of government, we may next explore the application of it to certain broad segments of society. The medical profession is, by its very nature, a service group to society and, as such, cannot escape being an important element in any system of government that society may conceive. Here, however, comes a fine point that is perhaps the crux of the matter. It is entirely sound for society to make certain demands upon the medical profession and to make its needs known. But, as a mass, society knows nothing about medicine, nor does it possess any skills whatsoever beyond those of the individuals and groups of which it is comprised. As a mass, it has neither the knowledge nor other means whereby, to feed itself, or to minister to its own ailments or to direct its own growth with intelligence.

Yet, in a democracy, society possesses great

power and its wise direction becomes imperative. Since authority for such direction must be vested in individuals, there is always the danger that these individuals will bring to their office, or acquire in office, views that are conditioned or otherwise prejudiced with respect to the groups that actually constitute society.

It would seem to be desirable procedure for society, when it feels the need of medical care, to call the doctor. But, equally, it would seem to be desirable for the doctor, when he is called, to respond. Thus, there is a twofold responsibility of which, in our recent history at least, I am not too sure that either society or the doctor have met their share.

Clearly, this problem is one which both society and the medical profession might well resolve through the use of properly operating government. Yet, to do this, the medical profession first must recognize the specialty of administrative medicine and it should select and place its own trained and qualified men in the offices of government that will operate in its own control. And in turn society, in the broad sense that I am using the term, must acknowledge the importance and the propriety of such an arrangement.

Bear in mind, though, that I am not recommending the uncontrolled self-determination by the medical profession of the rôle of the medical profession as a part of society. Rather, I am recommending the integrated control of medical care through a system whereby the medical profession will be the principal and primary source for the origin and development of such measures as may be indicated. Coördination and adjustment of what the medical profession recommends with the needs and recommendations of other groups must be accomplished also within the structure of government, at a higher level.

Were the medical profession to pursue the policy of complete self-determination, it would achieve all of the faults of what I have previously referred to as a pressure group, where selfish interests are likely to dominate. To justify such a policy in relation to any single profession or occupational group would certainly imply an equal right for all other professions or occupational groups. It would be tantamount to claiming that the farmer should determine his own place in society without any integration or control, or that labor should do likewise—obviously impossible procedures if chaos is to be avoided.

These views I urge upon you as being more than idle fancy upon my part. I believe that they strike close to the heart of the problem

that now acutely confronts us. Specifically, the starting point is this: We need to think of the structure of things for the time we all await when the war is over. We need to have our plane for coördinated action well developed. We need not only to have the men to lead us, but also the men to carry on the complex job of designing and building our medical future and we need to have those men in positions of responsibility where they can work most effectively.

The medical profession frowns upon certain forms of practice as unethical, yet licensed physicians continue to so practice. The medical profession frowns upon "government intervention," but such frowning is not very likely to stop the government from meeting a popular demand for a medical care program. When the government starts such a program, who is going to devise it?

When the government wants physicians it will find them. I hope that they will be the right men, that they will be part of, and understand the practising medical profession; that they will be realists and not theorists in their approach. I hope also that the medical profession, by a forward looking attitude, will see to it that this becomes increasingly possible and that the physicians selecting or selected for the field of administrative medicine are chosen wisely and given the opportunities to work with, and the support of, the profession that the seriousness of their undertaking deserves.

To summarize: It seems clear that the time has come when the medical profession must move more realistically toward the construction of its place in a rapidly changing social structure. To do this, it should recognize the place and need for trained physicians in the administration of its own growth, and it should develop and utilize the forces of government in the belief that good government should serve the people.

LABOR AND HEALTH AND WELFARE ACTIVITIES

The Community Chests and Councils, Inc., 155 East 44th Street, New York 17, N. Y., has done a commendable job in indicating by implication in the title of a recent study that labor may be interested in portions of the programs of health and welfare agencies other than their financing. Replies from 105 cities to an invitation issued by Community Chests and Councils to its

member councils of social agencies and community chests to tell the story of their relations with labor, excluding fund raising matters, are summarized in a pamphlet entitled "Labor Participation in Organized Health and Welfare Activities Other Than Fund Raising." Price 25 cents. The record of the cities thus far, as reported, will hardly occasion dancing in the streets, but even to discuss the mechanics of securing labor coöperation is an encouraging sign. An interesting comment in the summary is to the effect that letters from several cities expressed the opinion that there was current "over-emphasis" on the whole question of labor participation—a conclusion probably warranted in some communities and wholly unwarranted in others where efforts in this direction have been feeble or not made at all.

THE EVALUATION SCHEDULE AND POST-WAR PLANNING

At present writing it is anticipated that several hundred counties and cities in the United States and Canada will submit *Evaluation Schedules* giving a record of practices and facilities for the protection of public health for the year 1943. The *Schedules* are to be forwarded to the American Public Health Association office by March 1. Some *Schedules* will be sent directly, others through the state department of health.

In these hopeful times with increasing confidence in the approaching victory of the combined forces of the United Nations on the world's battlefields, eyes are being focused already on planning for the future. A ready-made plan that can serve as the basis for charting the future in the field of public health is to be found in the pages of the *Evaluation Schedule* and the chart which is returned to the community following the grading of the *Schedule*. On this chart is visualized clearly the strong points

in a local health program as well as the weaknesses and inadequacies. No better start can be made toward public health advancement than through thorough study and discussion of the "red" marks on the grading chart. Here are the clues to the unmet needs.

In some communities there will be shortcomings to be strengthened in the control of syphilis. In others lack of beds for tuberculosis cases is the major need. But whatever or wherever the weak spot, the picture is there portrayed for all to see.

The first step in planning ahead is a knowledge of what is today. The inventory process made possible by community use of the *Evaluation Schedule* provides the makings of the necessary topographical map on which to plot the roads and the buildings and the practices which will lead to better health for more people in the immediate future.

WHAT ARE HEALTH DEPARTMENTS DOING ABOUT ACCIDENT PREVENTION?

This question is partially answered by the Subcommittee on Accident Prevention of the American Public Health Association, Donald B. Armstrong, M.D., *Chairman*, in *The Spotlight* for January.

The committee calls attention to activities in New York, Minnesota, New Jersey, Illinois, and Kansas, which have emerged thus far in the review it is now conducting of state patterns of organized home and farm safety programs. The full report of the committee will be awaited with interest.

It should be mentioned that *The Spotlight* is an informal newspaper published in the interests of the National Health Honor Roll by the Committee on Administrative Practice. Its circulation is limited to health officers, but copies of the January issue may be obtained on request to the Association at 1790 Broadway, New York 19, N. Y.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

The Principles and Practice of Industrial Medicine—*Edited by Fred J. Wampler, M.D.* Baltimore: Williams & Wilkins, 1943. 555 pp. Price, \$6.00.

This interesting and valuable contribution covers the important aspects of the whole field of industrial medicine in 33 chapters prepared by somewhat less than this number of specialists in the field.

Beginning with a very brief history of the subject, the volume includes such subjects as Appraisal and Control of Industrial Health Hazards, Accidents, the Medical Department and Medical and Nursing Services, the Industrial Health Program of the American Medical Association, the Effects of Temperature and Abnormal Pressure, Lighting and Vision, Fatigue, Toxic Compounds and the Medical Control of Such Industrial Exposures, Electricity, Occupational Diseases of the Skin and of the Lungs, Venereal Diseases and Their Control, Nutrition, Shock and Burns, Compensation, Rehabilitation, and Women in Industry.

It must be obvious to the reader that a volume presenting such an over-all picture of the problem of industrial medicine should be very valuable and that is true in the present case; in fact, this book is to be highly recommended to those who desire just such an over-all statement of the various aspects of the now large field of industrial medicine.

When one examines the content of some sections of the book in detail, it becomes apparent that certain of the authors must lack close industrial contact with the field about which they have written. For example, the section on "The Toxicity of Certain Or-

ganic Solvents in Industry" deals with relatively few of the important solvents, and omits much information of basic importance.

One chapter is devoted to the pneumoconioses and of this all but one and one-half pages are devoted to silicosis. The remaining page and a half are devoted to asbestosis, siderosis, and anthracosis. This is hardly a sufficient treatment of a subject very important to the industrial physician. Occupational poisonings of various kinds are presented by eight different authors in seven separate sections of the book. Under these conditions, it is difficult to present a subject without some repetition and certain important omissions.

These criticisms must not be given too much weight, however, for the book as a whole is a valuable compilation for the industrial physician and other workers interested in this important branch of public health. The format, typography, figures and photographs are of a high standard.

LEONARD GREENBURG

The Nature and Treatment of Mental Disorders—*By Dom Thomas Verner Moore, O.S.B., Ph.D., M.D.* New York: Grune & Stratton, 1943. 312 pp. Price, \$4.00.

This book is presented by the author to clarify the field of psychopathology for physicians, psychiatric social workers, and psychiatric nurses. It is divided into four parts dealing with "Psychopathology, Therapy of Psychological Analysis, Miscellaneous Techniques and Organic Emotional Disorders." At the end is an appendix giving "Classification and Definition of the Clinical Entities of Psychiatry."

The latter is based on the *Statistical Manual for the Use of Hospitals for Mental Diseases* published for the National Committee for Mental Hygiene, 1942, and edited by Dr. Clarence O. Cheney. In this book Father Moore has made a worthy effort to summarize a vast field of psychological and psychiatric theory, and has accompanied this summary with case material illustrating his use of theories in practical work with individual cases. The author is frank to utilize what he can of theories that these fields present. The reader is at liberty to go further if he wishes, but he is not encouraged toward a goal of therapy that is more than he can take in the face of his common sense and individual experience.

ESTHER L. RICHARDS

The Nutrition Front: Report of the New York State Joint Legislative Committee on Nutrition; Legislative Document No. 64, 1943. 286 pp.

There is much information on current phases of nutrition in this report, and the committee responsible for it has done a good job in stirring up interest in improved nutrition. The recommendations of the committee regarding support of nutrition, school lunches, etc., are excellent, and it is hoped they will be carried out. Unfortunately, the report is cluttered up with much misinformation in the form of "opinions" by "authorities" on subjects such as: "hidden hunger"; draftees rejected because of nutritional deficiencies; vitamin supplements to workers ("In one plant in particular I saw it (vitamin supplements) increase in six weeks the amount of production, the reduction of spoilage and accidents, the reduction of absenteeism, and the increase of the weekly wage; results . . . statistically significant"); "vitamin C . . . assists in the resistance of the body to nitro-amido poisonings . . . it stimulates the circulation of the

blood . . . we personally have never run any controls for observation in regard to the benefits from these vitamin C tablets." How true! This report is recommended only to those who can distinguish fact from fancy, though it will be of interest to all.

FREDRICK J. STARE

Careers in Public Health—By Adrian G. Gould; M.D. Chicago: Science Research Associates (1700 Prairie Avenue), 1943. 49 pp. Price, \$.60.

Those who are concerned with the preparation of young persons for careers in the field of public health will be glad to know that a serious attempt has been made through this publication to cover the subject from the standpoint of vocational guidance adapted for high school and college students. Most vocational and professional areas are better documented than public health has been, and the author is to be commended for this effort. It is not easy to write a comprehensive monograph which will orient a young person on the historical development of careers in public health and which will distribute the emphasis properly. There will be minor criticisms as to details in this presentation, but for the intended purpose of giving a young person an over-all view of the field it is to be commended. The manuscript is well linked with the reports available from the Committee on Professional Education of the A.P.H.A. and with similar reports from other professional societies. REGINALD M. ATWATER

Municipal and Rural Sanitation—By Victor M. Ehlers, C.E., and Ernest W. Steel, C.E. (3rd ed.) New York: McGraw-Hill, 1943. 449 pp. Price, \$4.00.

This book is a condensed reference work on the various aspects of environmental sanitation as applied to

municipal and rural areas. It is a useful volume for the sanitarian and others engaged in the application of public health preventive measures to civilian life.

This 3rd edition is marked by substantial additions and revisions in keeping with current practice in the sanitation field. The discussion on pasteurization in the chapter on milk sanitation has been expanded to include modern methods and controls. The chapter on food sanitation has been revised to give more adequate coverage to the inspection of food handling establishments. More recent and more complete information is given on the bactericidal treatment of utensils and equipment. Additional information is furnished on the classification of waters in which shellfish are grown. A description of the modern practice of sanitary land filling for garbage and refuse disposal has been added to the chapter on that subject. Additional data on incinerator design and operation are also furnished.

Recognition is taken of the rapid developments in the field of commercial air conditioning by the addition of this subject to the discussion on ventilation. Other topics covered in this book include insect and rodent control, plumbing, lighting, housing, industrial hygiene, the sanitation of schools and swimming pools, and miscellaneous other sanitary controls involved in the transmission or prevention of communicable disease and the promotion of social health and well-being.

It is unfortunate that the chapter on the general characteristics of water does not include the Public Health Service drinking water standards adopted in 1942. In the discussion on fluorine in water no cognizance is taken of the possibilities of the reduction in dental caries by the maintenance of a small fluorine content in the public water supplies. In the chapter on

water-carried sewage disposal there may well be a difference of opinion in some sections of the country as to whether cesspools customarily should be "dug deep enough to penetrate into ground water." It is believed that the discussion of cesspools could, to advantage, be amplified.

The book has been interspersed with more usable figures and data than previous editions. It is recommended as an excellent text for the student of sanitation and the practical worker in the field. ALBERT H. STEVENSON

Relaxation—By Josephine L. Rathbone. New York: Bureau of Publications, Teachers College, Columbia University, 1943. 157 pp. Price, \$1.75.

Miss Rathbone has written a popular treatise on the causes of tension and some of the way for relieving it. A secondary purpose has been to rally education to the assistance of medicine, for the author emphasizes that no one type of remedy will remove all of the causes of tension.

The first part of the book is devoted to a discussion of the relation of fatigue to tension, and of the physical and psychological causes of fatigue and their symptoms. The presentation of certain topics is worth particular mention. The integrated nature of the human organism, the appraising of health accounts, the description of causes of chronic fatigue, the value of goals which men set for themselves are topics which have been treated clearly for the popular reader. Certain discussions of the physiology of fatigue are likely to mean very little to most persons. Description of the chemical changes in a muscle during contraction is too technical and serves little purpose in this book.

Physical and psychological treatments for chronic fatigue, hence for the relief of tensions, are described in the second

half of the book. Full reference is made to the technic of producing relaxation as used by Dr. Edmund Jacobson. One may experience difficulty occasionally in following the discussion on treatments because of the author's excursions too deeply into marginal areas. The recommendations for attitudes towards play in adult life are sound.

One may conclude that relief of chronic fatigue may result from securing adequate rest and avoiding excessive activity of any type, and in many cases doing suitable muscular exercise. It is emphasized that these do not supplant the need for medical advice and service where such are indicated.

The book, especially the first part, is very readable and should prove useful to persons who are interested in the causes of tensions and some of the ways for relieving them.

GLENN W. HOWARD

Holt's Care and Feeding of Children—By L. Emmett Holt (16th ed.) New York: Appleton-Century, 1943. 321 pp. Price, \$2.00.

During the early days of the Babies Hospital in New York, according to the interesting biography of Dr. L. Emmett Holt by his son, Dr. L. Emmett Holt, Jr., and R. L. Duffus, one development of considerable novelty was the organization of a short training course for nursery-maids. Dr. Holt, the hospital's attending physician, took charge of this teaching and for one of his teaching materials prepared a "Catechism for Nurses" to cover the commonly met details of clothing, bathing, feeding, etc. The "Catechism," issued by the hospital in the form of a 4 page pamphlet containing 23 questions and answers, was taken into the community by the nurses as they graduated and soon became generally known. Demand for reprints reached such proportions that general publication became inevitable and the pamphlet was expanded

to a booklet of 66 pages, published under its present title in 1894. Seventy-five reprintings and translations into Spanish, Russian, and Chinese testify to the early need and continuing popularity of this book.

The present edition, the 16th, has been revised and enlarged by Dr. L. Emmett Holt, Jr., Associate Professor of Pediatrics, the Johns Hopkins School of Medicine. The book retains its question and answer form and touches on most of the subjects likely to interest those caring for children. In general, the advice given is simple and practical, although there are curious lapses. Not many mothers will want to take time to iron diapers nor are many likely to give up the advantages of tie shirts for those which "button down the front."

The book's most striking deviation from present-day trends, however, is in the field of habit training and guidance in general. Although some liberalization is evident, there are still heavy overtones of the rigidity which is now fortunately on the wane in most pediatric practice.

In an era which has witnessed great expansion in available medical services for well and sick infants, one wonders at the necessity for including quite so much material on diagnosis and treatment.

MYRON E. WEGMAN

Principles and Practice of Rehabilitation—By John Eisele Davis, Sc.D. New York: Barnes, 1943. 211 pp. Price, \$3.00.

The purpose of this book is to present the principles and practices of rehabilitation which have been found most successful with patients having neurotic and psychotic conditions. The author points out the need for a program of rehabilitation for the increasing number of individuals who are being sent to mental hospitals. He constructs the edifice of rehabilitation by using as building blocks the individual's wants,

interests, needs, and capacity. It is a usable psychology of practical rehabilitation, for it presents the syndrome of each mental disease and then outlines the types of recreational and occupational therapy most suitable to meet the needs of each condition. An important principle which is stressed is that of distinguishing "between those activities that do something to the patient and those activities that cause the patient to do something himself, for himself."

This book is highly recommended to physical, occupational and recreational therapists, educators, psychologists, and psychiatrists interested in the rehabilitation of those emotionally disturbed.

GEORGE G. DEAVER

Food Poisoning—Its Nature, History and Causation. Measures for Its Prevention and Control—By Elliot B. Dewberry. Foreword by Gerald R. Leighton, M.D. London: Leonard Hill Limited (17 Stratford Place, W. 1). Ill. with 30 figs., 1943. 186 pp. Price, \$3.75.

This compact volume is a valuable contribution to the subject of food poisoning. It is written in three parts, the first dealing with bacterial food poisoning; the second, with poisons (metallic, poisonous plants, poisonous fish and shellfish) and with food allergy. The third part discusses botulism. Two appendices deal respectively with the contamination and decontamination of foods by poisonous gases in war, and with the steps to be taken by medical officers in rural areas in suspected cases of food poisoning.

The section on war gases is timely and includes a two page table showing the grouping of the poisons as "irritant," "blistering," etc., the name of the gases, their effect on various foods, and the decontamination treatment of these affected foods. The first and third parts are introduced by a ten page

"historical" sketch, while tucked away in the text are many historical briefs or citations of illustrative incidents. These will interest all participants in public health educational endeavors.

We have been favored in 1943 with contemporaneous British and American publications titled "Food Poisoning." The reading of both books emphasizes the importance placed on staphylococcus food poisoning in the United States as compared to the light consideration of this subject in the Dewberry text. In the United States publication, 32 pages are devoted to a separate chapter captioned "Staphylococcus Food Poisoning." In the Dewberry text, only 3 pages are allotted to this subject. Two of these 3 pages are devoted to a discussion of nine cases which occurred in Leicester during 1942. This outbreak "was at once traced" to an American food product.

Dewberry discusses Salmonella, botulism, poisonous plants, poisonous fish, poisonous shellfish and poisonous metals in a detailed and interesting manner.

Chapter VII is devoted to the prevention and control of bacterial food poisoning and includes a sub-heading entitled "Paper Containers for Milk." This cites the New York State Agricultural Experiment Station recommendations concerning the production and handling of these to prevent "infection of milk."

Chapter XIX pertains to the prevention of botulism. In this section, the author emphasizes the need for adequate equipment to obtain the high temperatures such as are produced in steam pressure cookers. He closes the section on home canning and preservation by quoting a 1934 communication from Dr. K. F. Meyer: "If there is no pressure cooker available in home preserving of non-acid foods it is safer to substitute dehydration, salting or pickling for canning."

A short chapter on food allergy is of

interest. Many pertinent references appear supplemental to the chapters. These are combined into an "Author Index" preceding the "Subject Index."

The casual consideration of Staphylococci weakens this book as a complete reference text on this subject. However, the book does contain so much that is of interest and of value as to occasion the opinion that it is a desirable complementary adjunct to other texts on food poisoning.

R. V. STONE

Fundamentals of Nutrition and Dietetics: A Workbook—By *Alberta Dent*. (2nd ed.) New York: Wiley, 1943. 209 pp. Price, \$2.00.

Except for the words "a workbook," the title of this book is misleading. It is simply an "exercise book" to accompany an elementary course in home economic nutrition. If such a book is desired, this one will probably serve as well as any other except that it is printed in type that is too small for comfortable reading. There is nothing unusual or new about this book, and the reviewer is of the opinion that it is entirely too much on the side of "spoon feeding" for students of college grade.

FREDRICK J. STARE

Hospital Discharge Study—Hospitalized Illness in New York City (Vol. II)—By *Neva R. Deardorff, Ph.D., and Marta Fraenkel, M.D.* New York: Welfare Council of New York City, 1943. 349 pp. (Offset.) Price, \$1.00.

The second volume of this study analyzing the hospital care of more than half a million New Yorkers in 1933 is now completed. The first volume dealt with the patients, their ages, residence, diseases, conditions on discharge. In the second volume the emphasis is upon medical conditions and hospital care—the types and auspices of hospitals and the types of diseases cared for in them.

The third volume, still in preparation, will summarize the experience of the project in suggesting practicable methods of hospital morbidity reporting as a routine procedure. The three volumes with their separate emphases lay the groundwork for a meaningful system of hospital morbidity reporting. The entire study is a monument to the imagination and tenacity of purpose of those who fashioned a significant addition to social accounting out of the otherwise unemployed talent salvaged and developed by the Work Projects Administration.

MARTHA LUGINBUHL

Tuberculosis in the United States—Graphic Presentation, Vol. I—New York: Medical Research Committee, National Tuberculosis Association, 1943.

This publication presents in tabular and graphic form information concerning tuberculosis mortality for the United States as a whole, for each state, and for certain geographic divisions. The 3 year periods covered are 1919–1921, 1929–1931, and 1939–1941. The information is presented by age, sex, and color, three of the main factors associated with variations in the tuberculosis mortality. The tables and graphs are well arranged, clearly printed, and therefore easy to follow and use. The volume is to be highly recommended as a source of information. The wealth of material contained does not lend itself to review and can only be adequately appreciated by consulting the publication itself.

GAIUS E. HARMON

Elements of Medical Mycology—By *Jacob H. Swartz, M.D.* New York: Grune & Stratton, 1943. 179 pp. Price, \$4.50.

Anyone who has struggled with the identification of fungi will at once appreciate the practical approach of the

author and the excellent classification methods made available for diagnostic purposes. The illustrations and charts are commendable. The author, who is Assistant Professor of Dermatology at the Harvard Medical School, has balanced the diagnostic and treatment features in a manner which utilizes his own first hand experience and should be valuable to students and others seeking a comprehensive grasp of medical mycology. The volume is well documented from the literature from this country and abroad. Given such contributions as this work, the field of mycology in time may become as well understood as medical bacteriology.

REGINALD M. ATWATER

The Science of Nutrition—By Henry C. Sherman. New York: Columbia University Press, 1943. 253 pp. Price, \$2.75.

The Science of Nutrition is the latest of a series of distinguished monographs by Professor Sherman.

The author says in his preface that he has sought to summarize and evaluate "the present status of nutrition in as concise and impersonal a manner as possible." He has succeeded admirably in his purpose. This short book is unusual in giving both a careful presentation of the accepted facts of nutrition, and an extensive discussion of the place of the science of nutrition in our society. About half of the chap-

ters are devoted to the subject matter of nutrition, with considerable emphasis on the historical development and changing attitudes in the field of nutrition. "Technical terms are reduced to a minimum."

The second half of the book is largely spent in a discussion of the nutritional status of the nation, what the government can reasonably do to improve nutrition in the United States, and what rewards are likely to result from such improvement. The author argues most seriously and convincingly that only heredity and bacterial diseases are as important factors as nutrition in deciding the health, vigor, and longevity of man.

To document his conclusions that great benefits will be derived from an improvement in the nutrition of the nation, Professor Sherman draws extensively on experiments carried out with rats in his laboratory at Columbia University. He presents convincing evidence that a wide gap exists between the diet that is just adequate to prevent signs of frank deficiency and one that produces optimum nutrition.

On the whole this book lies somewhere between the nutrition textbook and the popularized account of the more superficial aspects of nutrition. By filling the gap between these two extremes it should attract readers from all branches of biology who are interested in recent advances in nutrition.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

The Operator Will Recover—
A hair-raising story of gasoline fumes from a flooded carburetor filling the well of a sewage pump and when set off by the spark from a control switch, blowing the pump house to bits, including a heavy concrete flooring. You'll have a more wholesome respect for present-day rationed gasoline after reading this.

BOGERT, C. L. Explosion Wrecks Pumping Station. *Sewage Works Engin.* 15, 1:8 (Jan.), 1944.

Quote—The Government Printing Office is today the largest single industry of its kind in America, if not the entire world. **Unquote.** That startling statement has so floored me that I don't remember much about the rest of the item except that the industrial hazards there seemed pretty well taken care of. Despite wartime paper needs the Congressional Record goes windily on!

BRANDT, A. D., and REICHENBACH, G. S. Lead Exposures at the Government Printing Office. *J. Indust. Hyg. & Toxicol.* 25, 10: 445 (Dec.), 1943.

They Need Better Diets—In a group of pregnant women it was found that only 10 per cent consumed diets which met recommended standards of protein content. Protein in the diet and the size of the infant were found to be related. In earlier reports in this study, the mother's food was shown to have a profound effect upon the health of the infant. Reprints of the three papers in the series may be obtained by writing the Harvard School of Public Health.

BURKE, B. S., *et al.* Nutrition Studies During Pregnancy. *J. Pediat.* 23, 5:505 (Nov.), 1943.

Peering Into the Future—Much can be done through health education to make us a healthier nation, and that is the direction in which future health administration will proceed, says one who has earned the right to his opinion.

DUBLIN, L. I. The Duration and Thereafter for Public Health Nursing. *Pub. Health Nurse.* 36, 1:3 (Jan.), 1944.

No One Is Immune to This—There is not much public health in this article, but it is a most readable account of a completely unbelievable racket. You will be amused but you will be left wondering when your particular job may become a tempting objective for a scalawag.

FRYE, J. G. Battling the Tank Repair Racket. *J. Am. Water Works A.* 35, 12: 1574 (Dec.), 1943.

It Was Excellent—What was? See subject of this paper.

HEAGERTY, J. J., and MARSHALL, J. T. State of Health of the People of Canada in 1942. *Canad. Pub. Health J.* 34, 12:529 (Dec.), 1943.

Hunt Out This Issue—As a warning against the use of the discredited pulmotor now parading under the name of "resuscitator," this paper should be known to all health workers, even those who may have only a remote interest in first aid and early care.

HENDERSON, Y. The Return of the Pulmotor as a "Resuscitator." A Back-Step Toward the Death of Thousands. *Science.* 98, 2556:547 (Dec. 24), 1944.

Why Dairy Products Are Scarce—You should have at tongue's end the information furnished in this authoritative statement, as a ready answer to

that subversive pest who snarls about the shortage of butter "because it is going to the Russians." Despite the greatest number of dairy cattle ever kept and an improvement in production per cow, butter is scarce chiefly because more people can buy it nowadays—thank God! The figures are here.

HULT, M. Availability of Dairy Products in Coming Months. *J. Am. Dietet. A.* 20, 1:12 (Jan.), 1944.

How Much Mental Ill Health?—

A survey of all the major surveys conducted and published during the last 15 years upon the prevalence, incidence, and expectancies of mental ill-health leads to the conclusion that such studies are basically incomparable and disappointing. If intelligent planning depends upon knowledge of the magnitude of the problem, then apparently we haven't a particularly strong need to lean on in this particular swamp of ignorance.

LEMKAU, P., *et al.* A Survey of Statistical Studies on the Prevalence and Incidence of Mental Disorder in Sample Populations. *Pub. Health Rep.* 58, 53:1909 (Dec. 31), 1943.

From Tobacco Mosaic to the Rickettsias—Though the author calls his five thousand word essay (with 93 references) a brief summary limited in scope, the chances are you will find in it plenty of meat for one evening's tussle with scientific English. But if you will sharpen your concentration you will be repaid for the effort.

LENNETTE, E. H. Recent Advances in Viruses. *Science.* 98, 2550:415 (Nov. 12), 1943.

Raw Milk Not the Sole Offender

—Packing-house workers have a habit of eating partially cooked meat, a finding which is suggestive in the epidemiology of Brucellosis in this occupational group. Do you suppose other food handlers are similarly addicted?

LEVINE, M. G. Brucellosis in Packing-House Workers. *J. Indust. Hyg. & Toxicol.* 25, 10:451 (Dec.), 1943.

Confident England—Since World War I, one-third of the population of England has been rehoused. Other improvements in national health are recounted, as a backdrop for the health protection schemes adopted during World War II. Despite the exigencies of the day, the British medical authorities bravely look to the future, and envision a comprehensive public medical service.

MACNALT, A. S. Britain's Development of Preventive Medicine. *Canad. Pub. Health J.* 35, 1:10 (Jan.), 1944.

Rats Are Persistent Beasts—

Exterior walls placed about old buildings in the hope of keeping out rats must be el-shaped with an underground flange extending out from the building if they are to be effective. Then all rats inside the building must immediately be killed.

PORGES, R. The Use of Curtain Walls in Rat Proofing. *Pub. Health Rep.* 58, 52:1881 (Dec. 24), 1943.

Salus Populi Suprema Est Lex

—Misconceptions, that social medicine is synonymous with (a) preventive medicine, and (b) socialized medicine, are ably and provocatively explored by an Oxonian professor. We are standing at the beginning of the third epoch in preventive medicine, he says, and he outlines the nature of the new socio-medical problems confronting health and medical leaders. He ends, "notably in the land of our most virile and victorious ally, there have been important experiments in social medicine and hygiene from which we have much to learn." He is not referring to the U.S.A., I take it!

RYLE, J. A. Social Medicine: Its Meaning and Its Scope. *Milbank Quart.* 22, 1:59 (Jan.), 1944.

Significant Quarter Century— Russia is a strange place. The poor, abused people there have no freedom—to buy patent medicines, nostrums, and expensively useless beauty aids—for the commissariats have charge of the production of all medical commodities. The miserable wretches are not free to be healed by nature-quacks, bone-benders, or faith healers, for the same commissariats control the schools for the training of all medical personnel. Incidentally, the commissariats have charge of health education, health promotion and recreation, medical services, and rehabilitation.

SIGERIST, H. E. Twenty-five Years of Health Work in the Soviet Union. *Am. Rev. Soviet Med.* 1, 1:67 (Oct.), 1943.

First Need Is a Good Water Supply—Water supply additions and improvements to the tune of eight hundred millions will be required when the war is over, say these surveyors of our sanitary needs.

STREETER, H. W., and RANERI, R. National Inventory of Needs for Sanitation Facilities. *Pub. Health Rep.* 59, 1:1 (Jan. 7), 1944.

Nowadays We Acknowledge Our Slums—Time was when the local chamber of commerce and city officials would scream to high Heaven that no

slums existed in the fair city of . . . (deleted by the censor), but all is changed now. Reasons are discussed.

TWICHELL, A. A. A Yardstick for Postwar Housing. *Pub. Health Nurs.* 36, 1:12 (Jan.), 1944.

Some Fat Children Eat Less—Here are two findings which will give you something to mull over: most high school students do not need as many calories as have been recommended for these ages, and variation in needs of individual students is so great that no average can be considered a reliable evaluation of adequacy. It would seem that the next move was the National Research Council's.

WEIL, D. G. Medical Evaluation of Nutritional Status. *Milbank Quart.* 22, 1:5 (Jan.), 1944.

Healthy Homes—Something about the progress in improving housing in the United States under the aegis of this association's committee is recounted for our Canadian brethren. Let's hope that the prediction—in the next peace era we can look forward to notable advances—comes true: there will be plenty of Americans who will do their best to hamper the work.

WINSLOW, C.-E. A. Housing and the Health Officer. *Canad. Pub. Health J.* 35, 1:1 (Jan.), 1944.

ASSOCIATION NEWS

PROFESSOR WINSLOW ASSUMES EDITORSHIP

AS the JOURNAL goes to press, the Editorial Board is able to announce the appointment of Professor C.-E. A. Winslow as Editor of the JOURNAL, beginning with the April issue, and succeeding Dr. Harry S. Mustard whose resignation as Editor is announced in the editorial columns of this issue.

Professor Winslow has been and is so closely identified with Association affairs, through the Committee on Administrative Practice, which he served as Chairman for 15 years and the Committee on the Hygiene of Housing, which he has chaired since its creation 7 years ago, as to need no introduction to JOURNAL readers. His other Committee and Section connections have been numerous, and he has contributed regularly to the Annual Meetings and the

JOURNAL. He was elected President of the Association in 1926, and received a 40 year membership certificate and the Sedgwick Memorial Medal in the same year, 1942.

He is as well known among heating and ventilating engineers, bacteriologists, and housing experts as to public health workers. His bibliography is long and impressive, including hundreds of articles, pamphlets and such books as *The Life of Hermann M. Biggs*, *The Evolution and Significance of the Modern Public Health Campaign*, *A City Set on a Hill*, *Health on the Farm and in the Village*, and *Health Under the "El."* His latest book is *The Conquest of Epidemic Disease*.

Professor Winslow is Anna M. R. Lauder Professor of Public Health at Yale University, New Haven, Conn.

EXECUTIVE BOARD MEETING

THE Executive Board of the American Public Health Association met in New York on January 28 and discussed many important Association matters. Present were Abel Wolman, Dr. Eng., *Chairman*, James A. Doull, M.D., Hugh R. Leavell, M.D., Edward G. McGavran, M.D., Charles F. Wilinsky, M.D., C. C. Young, D.P.H., and Reginald M. Atwater, M.D., Executive Secretary. Unable to be present were Louis I. Dublin, Ph.D., the Treasurer, John J. Sippy, M.D., President-elect, and Felix J. Underwood, M.D., President.

The Board reviewed Association affairs since the Annual Meeting and was gratified with the favorable financial position at the end of 1943. Total income for the year was \$194,479.25 and total expense \$186,007.39. Association membership has reached a record high of 8,022, representing a net gain of about

800 members during the year. Appreciation was expressed to the members and Fellows who contributed to this gain by submitting the names of prospective members. The total *Journal* circulation now exceeds 11,200 copies each month, an increase of almost 10 per cent in January, 1944. The Board recognized the increased activity in the Book Service, the Information Service, and the Employment Service, as well as in all other departments.

The resignation of Dr. Harry S. Mustard as Editor of the *American Journal of Public Health* was received with deep regret and a resolution expressing appreciation to Dr. Mustard for his extraordinarily effective leadership during his term of service was unanimously approved. An editorial on his retirement appears elsewhere in this issue.

There was unanimous agreement that

AMERICAN PUBLIC HEALTH ASSOCIATION EXECUTIVE BOARD MEETING,
JANUARY 28, 1944

Left to right: Standing: Hugh R. Leavell, M.D., Louisville, Ky.; C. C. Young, D.P.H., Lansing, Mich.; James A. Doull, M.D., Cleveland, Ohio; Edward G. McGavran, M.D., Clayton, Mo.; Reginald M. Atwater, M.D., Executive Secretary. Seated: Charles F. Wilinsky, M.D., Boston, Mass.; Abel Wolman, Dr.Eng., Baltimore, Md. (Absent: Louis I. Dublin, Ph.D., New York, N. Y., Treasurer; John J. Sippy, M.D., Stockton, Calif., President-elect; and Felix J. Underwood, M.D., Jackson, Miss., President.)

there should be an Annual Meeting in 1944, and the Executive Board approved in principle a meeting in Chicago. Recognizing that suitable dates and hotel arrangements may be difficult to secure in that city, the Board voted to accept an invitation to hold a War-time Conference in New York City if space and time offer insuperable obstacles in Chicago. The membership will be advised when a definite decision is reached.

Authorization was given for the participation by the Association in the publication of a *Glossary of Terms for Use in Water Control Engineering* in collaboration with the American Society of Civil Engineers, the American Water

Works Association, and the Federation of Sewage Works Associations.

Enthusiastic approval was given to a "repeat performance" of a series of meetings in the Midwestern and Western states in May and June, and plans are going forward which give evidence that the second tour will be as successful as the first.

It was pointed out that the 15th Annual National Health Honor Roll will be concluded this April with the expected participation of about 100 cities and counties. Beside this number at least 150 communities in 14 states will also submit schedules as the result of an effort to interest those communities which did not wish to enter a competi-

tive contest yet were desirous of preparing an inventory of health assets and liabilities for national grading and comments. It seems that the Contest plan, carried on over the years, has laid the foundation for the next desirable objective, namely, the formation of a national reporting area for health practices. This new plan had brought out a favorable response from the state health departments in the 14 states reached, a response that was not forthcoming under a continuation of the Contest or Honor Roll plan. This will involve the direct participation of state departments of health both in urging the annual inventory upon the communities and in the distribution of schedules, as well as in the return of filled out schedules through the state departments of health. The public reception of the recent publication, *Health Practice Indices*, has been most cordial.

Appointments were made to the Standing Committees and these will be covered in the Committee List which will appear in the April *Journal*, together with other committee appointments and Section appointments which were confirmed.

The resignation of Dr. Henry F. Vaughan as Chairman of the Committee on Administrative Practice was regretfully received. The Executive Board acknowledged the Association's indebtedness to Dr. Vaughan for his able leadership and expressed the hope that his health would soon permit him to resume active participation in Association affairs.

Gratification was expressed with the progress being made by the Merit System Unit of the Committee on Professional Education in making examination material available to an increasing number of states, a service for which the federal agencies have indicated continued approval and appreciation. To date more than 65 examinations have been prepared for 14 states and 1 city.

The Executive Board considered at length the subject of public medical care and its relationship to the public health profession. It appointed Hugh R. Leavell, M.D., as its representative to review this field. Dr. Leavell has chosen to identify himself for the present with the new Subcommittee on Medical Care of the Committee on Administrative Practice which met on February 11.

Consideration was given to the possibility of broadening participation in the election of Association officers, and the Executive Secretary was instructed to present to the Governing Council in advance of its next meeting a report outlining several choices of methods which may be more acceptable than the one employed at present.

The applications of 12 concerns for Sustaining Membership were approved, bringing the total of Sustaining Members in the Association to 33. Those elected at the meeting were: American Bottlers of Carbonated Beverages, The Borden Company, Clay-Adams Company, Inc., Effervescent Products, Inc., Hoffman-LaRoche, Inc., Holland-Rantos Company, Inc., International Equipment Company, The Macmillan Company, Sealright Company, Inc., E. R. Squibb & Sons, The Upjohn Company, and the Winthrop Chemical Company. The Executive Board received with appreciation a contribution to the work of the Association from the Ciba Pharmaceutical Products Company, Inc.

The matter of adequate compensation for professional public health personnel, in line with the qualifications for various classes of public health workers established by the Committee on Professional Education, was discussed. The Executive Secretary was authorized to seek the aid and support of other professional societies with an aim to establishing adequate salary scales.

STANDARD METHODS FOR THE EXAMINATION
OF DAIRY PRODUCTS

* * *

*Corrections in the Text of the Eighth Edition of Standard Methods
for the Examination of Dairy Products*

The following corrections are being incorporated in a reprinting of the Eighth Edition of *Standard Methods for the Examination of Dairy Products*. They are reproduced here so that those possessing copies of the Eighth Edition may make the corrections therein. There are no other changes in the reprinting.

Separates of the corrections are available and may be received on request to the Association office, 1790 Broadway, New York 19, N. Y.

Page 8. Insert the following sentence between "gauge" and "Use," 2nd line "To insure sterility, rely upon the temperature in the autoclave rather than upon the pressure."

" Insert sentence following line 9, as follows: "In emergencies, suitable pressure cookers may be substituted for autoclaves."

" Line 10. Insert "or pressure cookers" after "sterilizers" at end of line.

Page 10. Change lines 4-10 to read "Clean cold water for rinsing the stirrer and (1) another can containing hot water kept continuously at not less than 180° F. by passing live steam through it, or (2) another can containing a hypochlorite solution (strength maintained at not less than 100 parts per million of available chlorine) for the practical sterilization of the stirrer. Rinse the stirrer first in cold water and then allow it to stand in the hot water or chlorine solution while making preparations to take the next sample (Figure I). Where plate counts are made on the collected samples, plate samples of the sterilizing solution each day when sampling is completed."

Page 19. Add new sentence just before the last sentence of the first complete paragraph: "Bottles with screw cap closures may be used where leak proof closures are assured. (These may require new liners in caps after each use.)"

" Insert an additional sentence at end of paragraph under "3. Petri Dishes" "Remove plates from containers when these are placed in the incubator chamber in order to permit plates to reach the incubation temperature promptly."

Page 20. Fifth line from bottom. Insert "anhydric" between the words "use" and "incubators."

" Third line from the bottom insert between "high" and "because" "(or equivalent space)."

Page 21. Line 2. Section 8. Water. For the word "distilled" in the second line of this paragraph substitute "buffered phosphate dilution water prepared, in conformity with Section K, page 126." This brings the Dairy Products requirements for dilution water into conformity, with the statement in *Standard Methods of Water Analysis*, Section XII, page 156 and Section V, page 207.

Page 24. Last line delete "containing unmeasured quantities."

- Page 27. End of Section 4, add new paragraph reading "Use a separate sterile pipette for each sample and for each dilution. Do not rinse pipettes in dilution waters."
- Page 28. Section 6. Cleaning Pipettes. Rewrite as follows:
 "Because improperly cleaned pipettes may cause incomplete deliveries, thoroughly wash pipettes with suitable detergents after each use and periodically soak them overnight in a strong cleaning solution. A bichromate-sulfuric acid cleaning solution may be prepared by adding 50 gm. sodium bichromate to 200 ml. of water in a glass or earthen container, and then cautiously add 300 ml. of sulfuric acid, commercial grade or Babcock testing grade. Wash acid-treated glassware thoroughly in alkaline waters and then thoroughly and repeatedly rinse in clean water. Tests on the rinsed glassware for presence of residual acid or alkali may be made by using appropriate indicators, such as brom thymol blue, Andrade's, etc."
- " Last line change "42°" to "44°."
- Page 29. Line 10, add sentence reading: "Where clay tops are used, inversion of plates during incubation is unnecessary."
- " Under VI. Incubation, change first sentence to read: "Arrange plates or piles thereof on the shelves of incubation chambers so that they are separated horizontally from each other and from the top and walls of the chamber by at least 1 inch."
- Page 30. Line 6. Add to paragraph "Accurate maximum and minimum recording thermometers or automatic temperature controlling and recording devices may be found desirable and may be used."
- Page 31. Rewrite as follows:

I. SELECTING SUITABLE PLATES

After incubation of two plates per sample, one from each of two dilutions, it is expected that the number of colonies on at least one, and perhaps occasionally both plates, will be between 30 and 300.^{33, 34} The optional use of more than two plates per sample is allowed. These extra plates may be either of the same or of different dilutions. Count all colonies including those of pin point size and include them in the officially reported count.

Report as the standard plate count the number of colonies on the plate yielding between 30 and 300 colonies (or the average if the number on both plates is within the limits) except (1) where more than one plate per dilution is made and (2) where there are no plates with colonies within the 30 and 300 limit.

(1) If two or more plates are made from the same dilution and only one has colonies within the 30 to 300 limit, use the others of the same dilution to determine the average count. In certain rare instances, this might include the counts from successive dilutions as some plates of the lower dilution might have less than 300 colonies and others more than 300, while some plates from the higher dilution might have more than 30 colonies and others less. In such cases use the average of all of the plates.

(2) Use the plate with nearest 300 colonies for the standard plate count if the dilutions selected are too low to give colonies within the 30 to 300 limits. Use counts from plates with less than 30 colonies only when no other plates are available.

Regardless of any of the above requirements, if the number of colonies developing on the suitable plates from successive dilutions is such that the higher count is more than twice the lower count, use the count or counts from the plate or plates which give the lower

count. Normally these will be the plate or plates with the number of colonies nearest 300.

Page 32. At top of page 32 start new paragraph with first sentence "If the number of colonies . . ."

" End of first partial paragraph add "If none of the plates show colonies, report the result of the analysis as unsatisfactory."

" Under 2. Counting Aids, change fourth complete sentence 2nd line above cut to read: "Examine carefully any doubtful specks in the agar using additional magnification where required to distinguish colonies from dirt specks."

Page 33. Under 4. Spreading Colonies, delete 2nd sentence which reads: "Count each as a single source." Insert the following in place of the 3rd complete sentence to read: "The first type is a chain or chains of colonies which appear to arise from the disintegration of more or less compact clumps of bacteria found in the milk. If but a single chain of colonies is formed count the chain as one. If several chains are formed count the approximate number of chains. Do not count each individual colony as one."

" "In the second and third types of spreaders, count each spreader as a single source. Discard plates where the spreader covers more than half of the plate."

Page 35. Under 5. Estimating Colonies on Crowded Plates, substitute the following for all except the last sentence: "Where the number of colonies on the plate appreciably exceeds 300, count colonies in portions of the plate representative of colony distribution and estimate therefrom the total number on the plate. Where there are from 5 to 10 colonies per sq. cm. area, count the colonies in from 12 to 14 different areas, selecting, if representative, the 6 consecutive squares diagonally across the plate and the 6 consecutive squares, at right angles to the first diagonal. Where there are more than 10 colonies per sq. cm. area, count colonies in 4 such sq. cm. areas, selecting, if representative of colony distribution, the 4 areas near the center. Multiply the average per sq. cm. area as found by the appropriate factor, to obtain the number of colonies per plate."

Page 46. Line 1 under Figure XI, change "Spread the films either" to "Spread the films evenly."

Page 52. Line 10, end sentence with "rapidly." Delete "or" and start next sentence with "Otherwise."

Page 64. Line 5 from bottom, change "visual" to "visible."

Page 79. Second paragraph, second sentence under Presumptive Test, 12th line from bottom of page, change to read: "In pasteurization control, for example, 5 tubes or even 3 tubes each inoculated with 1 ml. (or 10 ml.) are sufficient where frequent routine analyses have shown that results are likely to be negative. In this work as in bacterial count work, a simple examination of routine samples taken frequently will give more useful information than a more complete examination of samples taken at infrequent intervals."

Page 107. 4th complete paragraph 13th line from bottom of page change "The National Aniline and Chemical Company" to read: "The National Aniline Division of the Allied Chemical Company."

- Page 128. Substitute the following for the statement in line 15 beginning: "20 times the number of colonies" to read "10 times the sum of the number of colonies on the two plates receiving 1 ml. each of rinse solution, or 100 times the sum of the number of colonies on the two plates to which 0.1 ml. each was added, equals the estimated number of colonies per bottle."
- Page 195. First line "45 ml." not "45 gm."
4th line under 3. Dried Eggs. "99 ml." not "99 gm."
- Page 267. Line 5 under C. Apparatus, insert "C." after 34°-37°.
- Page 271. Under C. Apparatus, line 1, pipettes, line 2, tubes. Line 3—tubes, 150 x 15 mm.
Under D. Permanent Color Standards—a. Color solution red, delete—"0.58."

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Francisco Berio-Suarez, M.D., Comerio, Puerto Rico, Public Health Officer
Eugene S. Brown, M.D., Summersville, W. Va., Nicholas County Health Officer

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

Wanted: A physician trained in tuberculosis to assume administrative control of the Bureau of Tuberculosis in an eastern city of 200,000 population. Salary \$3,900-\$4,500 plus cost of living adjustment. Address Box B, Employment Service, A.P.H.A.

Sanitarian wanted: Preferably with Bachelor's degree or engineering degree, plus public health experience or training. Must have own car. Applicant with lower qualifications will be offered an opportunity to take a short, free indoctrination course. Salary \$1,920 per year with travel allowance of \$50 per month, if qualified. Apply Dist. Dept. of Health, No. 6, Central Office, Newberry, Mich., Dr. Franklin.

Wanted: Pediatrician to supervise medical care of children at cerebral palsy center being established by private institution in coöperation with Illinois Division of Services for Crippled Children. Salary commensurate with experience and training. For further information write Lawrence J. Link, Director, Division of Services for Crippled Children, 1105 So. Sixth St., Springfield, Ill.

The Department of Health, New Jersey, whose industrial health activities have expanded rapidly during the present war, has announced its need for two full-time industrial hygiene physicians for its Industrial Hygiene Service. As one of the leading states in the production of war materials, New Jersey offers unusual opportunities for gaining experience in occupational disease control besides giving the physician a chance to make a valuable contribution to the war effort. The principal duties of the selected physicians will be consultations in regard to the following: control of occupational diseases; industrial toxicological problems; evaluation of adequacy of plant medical services; promotion of measures which will reduce absenteeism from non-occupational causes; and conduct of industrial health education activities. Phy-

sicians interested in these positions should write to the Department of Health, Trenton, N. J.

Merit System for Personnel Administration in Delaware will set examinations for 3 positions in the Delaware State Board of Health shortly. The positions open for examination, together with the beginning salaries, are: Deputy State (County) Health Officer (\$3,800), Pediatrician (\$3,600), and Medical Social Consultant (\$2,400).

These examinations will be unassembled, but successful candidates will be expected to appear in Delaware for an oral interview which will be a weighted part of the examination. Appointments may be expected soon after the examinations are conducted.

Information and specifications as prepared for each position may be secured by communication with the Merit System Supervisor, P. O. Box 1911, Wilmington, Del., and application for examination must be made on the official form.

The Milwaukee Health Department is interested in obtaining an instructor in hospital nursing to conduct a student educational program in its communicable disease hospital. Salary offered begins at \$125 per month with maintenance, and increases of \$5 per month each year until \$135 has been reached. To this basic salary there has been added a cost of living bonus of \$30.64 per month, making the total beginning salary \$155.64 plus maintenance. Apply to Dr. G. F. Burgardt, Deputy Commissioner of Health, Milwaukee, Wis.

Wanted: Public health physicians in Texas. George W. Cox, M.D., State Health Officer, Austin, Tex.

Hawaiian Territorial Board of Health seeks trained engineer to supervise rodent plague control program. Salary range from \$331.67 to \$398.33 per month subject to retirement deductions plus bonus. Position under Territorial civil

service system with classification of P-4. For further details address A.P.H.A. Employment Service.

Wanted: Physical therapist by Crippled Children's Division. Should be graduate of a school of nursing or of college, with a major in physical education or science; have completed a course in physical therapy; should have had experience in physical therapy, preferably with children. Write for application blank to Merit System Council, 416 Henry Building, 309 S.W. 4th Ave., Portland 4, Oregon.

Psychiatric case worker desired for mental hygiene clinic, Department of Health, Peoria, Ill.

Senior Sanitarian, Alaska Health Department. Minimum requirements 2 years college, 6 months public health course, 2 years' experience. Two additional years' experience acceptable instead of each year college. Monthly salary \$235-\$265. Mary B. Pool, Alaska Merit System, Juneau.

Michigan announces civil service positions now open for orthopedic public health nurse, Grades II and III classes with the Michigan Crippled Children's Commission. Salary range: Grade II, \$230 to \$270 per month; Grade III \$280 to \$340 per month. Grade II not under 23, Grade III not under 25. Must have completed course in orthopedic nursing or physical therapy in approved school. For Grade III position a full-time course of at least 9 months' duration is required. Must have 3 years' experience in public health nursing, one year of which shall have been in supervisory capacity. For Grade III position one additional year of nursing and one additional year of supervisory experience required. Eligibility for certificate in public health nursing and registration as a nurse in Michigan. For further information write Michigan Civil Service Commission, 310 No. Grand Ave., Lansing 4, Mich.

Industrial Hygiene Toxicologist. Calls for person of chemical or chemical engineering background. Position, supervising of chemical work of industrial hygiene service and industrial hygiene laboratory; designing special apparatus for field studies on occupational disease problems; conducting field and laboratory analyses of toxicological exposures in industry; keeping records, interpreting results and preparing records. Requirements, knowledge of chemical laboratory methods and equipment; procedures for qualitative and quantitative analysis of organic and inorganic chemistry; knowledge of chemical methods of determining

toxic materials in industry; familiarity with petrographic methods of mineralogical analysis. Immediate temporary appointment will be made, to be followed later by civil service examination to determine permanent status. Salary \$2,900 base, plus \$100 a year war adjustment, or total of \$3,000 per year. Travel expenses also allowed. Must be U. S. citizen. Resident of any state may apply. Write J. Lynn Mahaffey, M.D., Director of Health, State Department of Health, Trenton 7, N. J.

Wanted: Public Health Nurse. Salary \$175 per month and full maintenance, plus \$25 per month for car expense. Must furnish own car. Write Paul D. Crimm, M.D., Director Boehne Tuberculosis Hospital, Evansville 12, Ind.

MISCELLANEOUS

Public Health Nurse. B.S. in nursing, William and Mary College, age 53, seeks position as coördinator of public health nursing, educational director, or director student nurse public health program. Prefers Middle Atlantic States. M-452

NEWS FROM THE FIELD

NEW YORK STATE TRAINS SUBSTITUTE ENGINEERING PERSONNEL

According to the New York State *Health News*, the New York State Department of Health, as a wartime measure to meet a serious public health problem caused by a shortage in the ranks of its sanitary engineers, has evolved a plan calling for intensive on-the-job training of graduate civil engineers, the first 6 of whom have already been appointed. During the early months of the war promotions of junior engineers replaced 14 key men who were called to the military services, but replacements for 8 district sanitary engineers now expecting calls to the service have proved very difficult. After a canvass of practically the entire country, 8 graduate engineers have been obtained to fill the unexpected vacancies. They will be trained in public health engineering and will handle the work of this nature in the districts to which they will be assigned under the supervision of sanitary engineers in adjacent districts. Other unfilled vacancies remain to be filled.

DISTINGUISHED SERVICE MEDAL AWARDED TO BRIGADIER GENERAL LEON A. FOX

Brigadier General Leon A. Fox, M.C., U.S.A., F.A.P.H.A., was recently awarded the Distinguished Service Medal for "exceptionally meritorious and distinguished service in a position of great responsibility while serving as Health Director for the Caribbean and North Atlantic Engineer Division . . . During this period, in addition to his normal duties as Division Health Director, General Fox was charged with carrying out a health program of great magnitude in connection with construction work in the Caribbean

bases, northern ferry routes, ferry routes across Africa, Pan American highway, Northwest Division and foreign missions located in Africa, Iran, and Iraq. Throughout, General Fox has demonstrated great foresight, energy, organizing ability, and inspiring leadership, which have contributed in large part to the successful prosecution of these important projects," according to a report in the *Journal of the A.M.A.*

RESEARCH FUND HONORS DR. VERANUS A. MOORE

President Edmund E. Day of Cornell University, Ithaca, N. Y., recently announced the endowment of a scholarship to be known as the Veranus A. Moore Research Fund. It has been established through an anonymous gift of \$10,400 in honor of the memory of the former Dean of the State Veterinary College, Ithaca. The income from the fund, according to Dr. Day, will be used for research in clinical and preventive medicine.

Dr. Moore joined the American Public Health Association in 1896 and was a Fellow of the Laboratory Section. He died in 1931.

MEXICO CREATES A MINISTRY OF PUBLIC HEALTH AND ASSISTANCE

According to reports from Mexico City, the government has created a new Ministry of Public Health and Assistance effective October 15. Dr. Gustavo Baz is the Secretary or Minister. The Subsecretary is Dr. Manuel Martinez Baez; Chief of the Division of Public Health and Assistance in the States and Territories, Dr. Gustavo Viniegra; Chief of the Division of Public Assistance in the Federal District, Dr. Raul Fournier; Chief of the

Division of Maternal and Child Hygiene, Dr. Pedro Daniel Martinez; Chief of the Division of Epidemiology, Dr. Salvador Iturbide Alvirez; Chief of Division of Public Health in the Federal District, Dr. Salvador Gonzalez Reynoso; Chief of the Division of Foods and Drug Control, Dr. Demetrio Mayoral Pardo; and, in the Division of Sanitary Engineering, Engineer Luis Guerrero Arciniega.

Dr. Garza Brito continues as Dean of the School of Public Health and Hygiene.

Dr. Manuel Gonzalez Rivera is the Chief of the Division of Health and Education.

MASSACHUSETTS PUBLIC HEALTH

ASSOCIATION ELECTS OFFICERS

At its meeting on January 27 in Boston, the Massachusetts Public Health Association elected the following officers for the coming year:

President: Harold W. Stevens, M.D.

Vice-Presidents: L. Jackson Smith, M.D., and Charles F. Wilinsky, M.D.

Secretary: Alexander A. Robertson

Treasurer: Catharine Atwood

Executive Committee: Ethel G. Brooks, R.N., Manfred Bowditch, G. Donald Buckner, Roy F. Feemster, M.D., and Edwin H. Place, M.D.

Representative to the Governing Council of the American Public Health Association: Raymond S. Patterson, Ph.D.

Alternate: L. Jackson Smith, M.D.

DR. CRABTREE APPOINTED TO UNRRA

The press on February 1 carried the announcement of the appointment of Dr. James A. Crabtree, formerly of Tennessee, who has been identified with health and safety activities of the federal government since 1934, as Acting Chief of the Health Division of the United Nations Relief and Rehabilitation Administration. The appointment was made by Herbert H. Lehman, Director-General, UNRRA. Dr. Crabtree was graduated from the University of Tennessee in 1925 and took post-

graduate work at Johns Hopkins University School of Hygiene and Public Health in Baltimore.

TROPICAL MEDICINE COURSE ANNOUNCED AT DELAMAR INSTITUTE

Harry S. Mustard, M.D., the Director of the De Lamar Institute of Public Health, New York, N. Y., has announced that the Institute as a part of the College of Physicians and Surgeons of Columbia University would offer an intensive program of instruction in certain aspects of tropical medicine for a period beginning March 20 and continuing through May 13. Persons interested in the course should communicate with Dr. Mustard.

COLONEL BAYNE-JONES APPOINTED DIRECTOR OF TYPHUS COMMISSION

The War Department, Washington, D. C., recently announced the appointment of Colonel Stanhope Bayne-Jones* of the Army Medical Corps as Director of the Typhus Commission, succeeding Brigadier General Leon A. Fox* of the Army Medical Corps, who asked to be relieved as Director and to be appointed Field Director in order to give all his time to the field work of the Commission, which has been operating abroad, particularly in the Middle East. Colonel Bayne-Jones is also Assistant Director of the Division of Preventive Medicine, Office of the Surgeon General.

PERSONALS

Central States

WALTER H. HARTUNG, M.D.,* has been appointed Health Officer of Toledo, Ohio, according to the *Journal of the A.M.A.*, succeeding EARL E. KLEIN-SCHMIDT, M.D., DR.P.H.,* resigned. Dr. Hartung was formerly acting City

* Fellow A.P.H.A.

† Member A.P.H.A.

Health Director and State Health Officer. More recently he has been Director of the Medical Relief Bureau at the City Health Department. Dr. Kleinschmidt has joined the U. S. Public Health Service Reserve, Washington.

WILLIAM F. MAYES, M.D., has resigned as Director of the Division of Maternal and Child Health of the Kansas State Board of Health, Topeka, and has been appointed Regional Medical Consultant for the Children's Bureau, Washington. At present Dr. Mayes is located in the Kansas City District.

GEORGIA V. MILLS, M.D.,† of Detroit, Mich., has been appointed Deputy Health Officer of the Saginaw City Health Unit.

JOHN W. O'NEILL, M.D., of St. Charles, Mich., has been appointed Health Officer of District No. 5, including Nawaygo, Lake, and Oceana Counties, Mich., succeeding ALBERT C. EDWARDS, M.D.† Dr. O'Neill's headquarters will be in White Cloud.

JEROME J. SIEVERS, M.D.,* has been appointed Chief of the Division of Communicable Diseases in the Illinois State Department of Health, Springfield, effective January 1. Dr. Sievers has been Assistant State Health Officer and succeeds the late JOHN J. MCSHANE, M.D.

LARS W. SWITZER, M.D.,† of Manistee, Mich., resigned as Director of the Manistee-Benzie County Health Department December 1 to become associated with General Motors Corporation, Bay City.

JAMES F. WILSON, M.D.,† Rogers City, Mich., Health Director of District No. 4, has been appointed to a similar position with the Manistee-Benzie County Health Department.

Eastern States

MARK D. DUBY, M.D., has been appointed Health Officer at Schuylerville, N. Y.

LALLA MARY COGGANS,* former supervisor at the Lobenstine School for Nurse Midwives in New York, N. Y., has been appointed to the position of regional consultant nurse for the Children's Bureau in the southwest area, with headquarters in New Orleans. Miss Coggans was formerly the maternal and child health consultant nurse in the state of Florida. She is a graduate of Teachers College, Columbia University, and the Lobenstine School for Nurse Midwives.

GRACE E. LUTMAN, M.D., M.P.H.,† has been appointed assistant in the Department of Epidemiology at the Harvard School of Public Health, Boston. Dr. Lutman received her degree in 1942 at Harvard. She will assist DR. W. LLOYD AYCOCK in giving the course in epidemiology.

MRS. HAROLD V. MILLIGAN of New York, N. Y., has been appointed National Commander of the Woman's Field Army of the American Society for the Control of Cancer, according to an announcement made by DR. CLARENCE C. LITTLE, the Managing Director. Mrs. Milligan is President of the National Council of Women and recently has served as Director of the Women's Division of the National Association of Manufacturers, New York.

TERRY S. MONTAGUE, M.D., of Gouverneur, N. Y., has been appointed Health Officer of Watertown to succeed GEORGE D. VAN DOREN, M.D., who has retired.

RUFUS S. REEVES, M.D., has been appointed Director of Health of Philadelphia, Pa., and MEYER SOLIS-COHEN, M.D., has been appointed Assistant Director.

* Fellow A.P.H.A.

† Member A.P.H.A.

HUGH H. SHAW, M.D., Health Officer of Utica, N. Y., according to the *Journal of the A.M.A.*, on January 1 entered his 25th year as Health Officer.

Southern States

REUBEN B. CALDWELL, Baldwin, Miss., has been appointed a member of the State Board of Health to succeed JAMES W. LIPSCOMB, M.D., Columbus, President of the Board since 1932.

WILLIAM Y. GARRETT, M.D.,† of Eastville, Va., was recently appointed Health Officer of Newport News, succeeding DR. WILLARD W. GRIGGS, who resigned to enter private practice.

KENNETH M. LYNCH, M.D., who since 1940 has been Chairman of the South Carolina State Board of Health, has been appointed Dean of the Medical College of the State of South Carolina, Charleston, succeeding ROBERT WILSON, M.D., retired.

GEORGE N. MACDONELL, M.D.,† former Health Officer of Miami, Fla., has been appointed Chief of the Medical Service Division of the Dade County Defense Council. Dr. MacDonell succeeds DR. GERARD RAAP, Miami, who recently resigned because of ill health.

FRED MAYES, M.D.,† recently appointed Regional Medical Consultant of the Children's Bureau, Washington, has been assigned as Consultant for the Southeastern States with offices in New Orleans, La.

SHERMAN S. PINTO, M.D.,† New Orleans, La., Supervisor of the Industrial Hygiene Section of the Louisiana State Board of Health, has resigned to accept a commission in the Medical Corps of the U. S. Army.

DEAN W. ROBERTS, M.D., of Baltimore, Md., has been appointed Chief of the Bureau of Child Hygiene of

the Maryland State Department of Health, Baltimore, succeeding EDWARD DAVENS, M.D., of Baltimore, who is in military service.

CYRUS M. SHIPP, M.D., of Bay St. Louis, Miss., Director of the Hancock County Health Department, was recently chosen President-elect of the Mississippi Public Health Association, and JOHN B. GRANT, McComb, was installed as President.

BRIGADIER GENERAL JAMES STEVENS SIMMONS,* U. S. Army, Chief of the Preventive Medicine Service, Office of the Surgeon General, U. S. Army, on December 22 had conferred upon him, by the University of Pennsylvania, the honorary degree of Doctor of Science.

CHARLES P. STEVICK, M.D.,† of Beaufort, N. C., Health Officer of Cartaret County, has been appointed Acting Director of the Division of Epidemiology of the State Board of Health with headquarters at Raleigh. It is reported that Dr. Stevick will continue in this position for the duration.

Western States

LILLIAN M. HALL, M.D., has recently been appointed Health Officer of Concord, Calif.

RUDOLPH R. LANG, M.D., Passed Assistant Surgeon, U. S. Public Health Service, was assigned as Health Officer of Deschutes County, Ore., succeeding FREDERICK P. ROGERS, M.D., who is entering military service.

L. J. LULL, M.D.,* who has been Director of Venereal Disease Control in the Colorado State Board of Health, Denver, has resigned to accept an appointment with the Idaho State Department of Public Health, Boise, as Director of the Division of Local Health Service, effective January 7.

Immunity in Human Subjects Artificially Infected with Influenza Virus, Type B*

THOMAS FRANCIS, JR., M.D., F.A.P.H.A., HAROLD E.
PEARSON, M.D., JONAS E. SALK, M.D.,† AND
PHILIP N. BROWN, M.D.

*Department of Epidemiology and the Virus Laboratory, School of Public Health,
University of Michigan, Ann Arbor, Mich., and the Ypsilanti State
Hospital, Ypsilanti, Mich.*

EPIDEMIOLOGICAL evidence indicates that immunity to influenza is acquired by the human subject, presumably as the result of infection, but its duration has not been clearly established. During the winter of 1942-1943 an effort was made to gain further information on this point by studying the reaction of a group of individuals to induced infection with influenza virus, Type B, and determining the response of the same subjects to the same virus

four months later. The present report comprises the evidence obtained.

MATERIAL AND METHODS

Virus—The Lee strain¹ of influenza virus, Type B, was used throughout. The extra-embryonic fluid from infected hen's eggs, 48 hours after inoculation, was harvested and concentrated in physiological salt solution by the procedure of Francis and Salk.² For the first exposure, concentrate was used from the 20th and 21st egg passages after 8 passages in ferrets and 137 in mice. The material had been stored in the refrigerator at 4° C. for a month prior to use. In the second test similar material from the 34th and 35th egg passages was used after 7 to 16 days' storage at 4° C.

The titer of virus in the two lots of concentrate was determined by agglutination of chicken erythrocytes and by

* Presented at a Joint Session of the Epidemiology and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

† Fellow in Medical Sciences of the National Research Council.

NOTE: These investigations were aided through the Commission on Influenza, Board for the Investigation and Control of Influenza and other Epidemic Diseases in the Army, Preventive Medicine Division, Office of the Surgeon General, United States Army. This study was also aided by a grant from the International Health Division of the Rockefeller Foundation.

the intranasal infection of mice. Hemagglutinin titers were determined by a modification of the method described by Hirst.³ Five-tenth ml. volumes of twofold dilutions in physiological salt solution of the fluid to be tested were mixed with equal volume of 0.25 per cent suspension of washed fowl erythrocytes. The test was allowed to stand at room temperature for 1½ hours, when all the cells had settled, and then read by viewing the pattern formed at the bottom of the tubes. The end point was considered to be the highest dilution of virus which completely agglutinated all the cells. The titer is expressed in terms of final dilution of virus, after addition of cell suspension.

The titers of the two lots of material are as follows:

spraying was done in a small treatment room off the corridor leading to a large day room. After spraying, each subject was permitted to return to the large room where he mingled with the controls. Although the latter did not enter the treatment room, there was opportunity for atmospheric interchange between the spray room and the day room where both treated and control individuals congregated.

Subjects—The individuals participating in the clinical trial were residents of one ward of the Ypsilanti State Hospital, Ypsilanti, Mich. They were ambulatory males, many of them in the older age groups, who were confined to the ward except for a daily walk outdoors or occasional tonsorial expeditions. Since no preliminary information as to

Numerals indicate day of death after inoculation

± to +++++ indicate different degrees of pulmonary consolidation at autopsy on 10th day

Method of Infection—The nebulizers used contain glass baffles against which the material to be sprayed is blown. The result is almost a dry mist which condenses on a cold surface with fine, uniform coating. The instruments were attached by rubber connections to a tank of compressed air and 10 lb. pressure was applied. Under these conditions the different nebulizers delivered 0.1 to 0.17 ml. per minute. Glass nasal adapters were attached to the dispensing end of each nebulizer and were inserted into the nostril. The spray was inspired by the subject through one nostril for 2½ minutes and then for the same time through the other nostril. In the process of spraying, the patient exhaled a large proportion of the material which settled as a fine cloud. The adapter was washed with antiseptic solution before use by another subject. The

their serological levels was obtained, no selection on this basis occurred. There had been no evidence of heightened incidence of respiratory disease in the previous 8 months. All were carefully examined for signs of acute respiratory illness before being included in the group.

Clinical Observations—At the time of the first spray, records of rectal temperature were begun the day after inoculation and continued until the temperature reached normal. In many instances satisfactory stories of the individual's symptoms could not be obtained but attendants familiar with the customary behavior of the subjects were able to recognize significant modifications in this respect.

Previous to the second test, temperatures were taken *per os* for 2 days; thereafter rectal temperatures were

taken. In addition, from 9 men receiving virus a second time and from 9 receiving virus for the first time, leukocyte counts were obtained on the day before and the 2 days succeeding the spray.

Laboratory Studies—Venous blood was collected from each individual immediately before and 14 to 16 days after spraying. The sera were examined at one time for the titer of antibodies to the Lee strain of virus, using a modification of the agglutinin-inhibition test of Hirst.⁴ The modified test* involves the use of a 0.25 per cent suspension of fowl erythrocytes in which the serum dilutions are made directly and the result is read by the sedimentation pattern obtained after complete settling at room temperature. To 0.5 ml. dilutions of the serum in the 0.25 per cent red cell suspension is added 0.5 ml. of virus dilution corresponding to twice the agglutinin titer, thus giving a mixture which contains one unit of hemagglutinin. The end point chosen is the last tube showing complete inhibition of agglutination and is expressed in terms of the final serum dilution, after the addition of virus. The lowest serum dilution tested in the routine test was 1:32, since significant changes in titer are usually well above this level. However, in a few instances lower dilutions were tested.

Throat washings were obtained 48 hours after inhalation from half the individuals sprayed in the first test but, owing to an accident, were rendered unsatisfactory for conclusive study. No virus was detected in samples examined for the presence of red cell agglutinins or tested by ferret inoculation. In the second experiment garglings were collected 24 hours after the spray from 19 receiving a second inoculation, from 10 receiving their first exposure and from 2 untreated controls. The samples were

kept on dry ice until tested 10 days later. Each specimen was injected into the nostrils of 5 anesthetized mice which were reinoculated with sterile broth by the same route 4 days later. All animals were sacrificed on the 11th day and their lungs examined for virus lesions. A few samples were also examined for their capacity to agglutinate chicken's erythrocytes. The results are discussed in the text.

Dissemination of Virus—At the time of the second spraying experiment, 10 mice in a box of wire mesh were placed in the room where the inhalations were administered. Another set of 10 was placed on the floor in the ward where the men congregated after spraying. They were kept in these locations for 4 hours and then transported to the laboratory. Two days later, half the mice of each group were inoculated intranasally with sterile broth, and all were observed for signs of infection with influenza virus.

EXPERIMENTAL

INFECTION OF HUMAN SUBJECTS WITH INFLUENZA VIRUS, TYPE B

Clinical Evidence—On November 28, 1942, 60 individuals inhabited the ward. Thirty were designated to serve as untreated controls; the remaining 30 were divided into three groups of 10. The first group was sprayed with virus which had been concentrated and then diluted to the strength of the original material; the second, with virus concentrated twofold; the third group received virus which had been concentrated tenfold. In the next 24 hours, 27 of the 30 individuals receiving the sprayed virus exhibited fevers of 100° F. or greater. In 20 instances the temperature was 101° F. or greater. The data presented in Table 1 indicate that the severity of febrile reaction was somewhat related to the amount of virus received. Thus, 6 of 10 receiving the smallest dose had temperatures of

* Details of the procedure are soon to be published.

TABLE 1

Febrile Response to Spray with Different Doses of Influenza Virus, Type B

Group	Dose	Maximal Temperature (per rectum)			
		<100° F.	100°-100.9° F.	101°-101.9° F.	102°+ F.
1	Unconc.	1	5	1	3
2	2 x Conc.	1	2	3	4
3	10 x Conc.	1	0	2	7
	Total	3	7	6	14

less than 101° F. whereas, 9 of the 10 given the largest concentration of virus had fever of 101° F. or greater. The temperatures of those receiving the intermediate dose were more widely distributed.

From 14 subjects in the series there were either no complaints or information was not obtainable. Among the remaining 16 the following symptoms were noted:

Chills or chilliness.....	14
Loss of appetite.....	9
Nausea.....	5
Malaise.....	4
Headache.....	2
Nausea and vomiting.....	2
Body aches.....	1

Seven of the patients took to bed. It should be observed that coryza, sore throat, and productive cough were essentially absent.

Physical examination revealed little. No evidence of pulmonary involvement was noted.

The period of illness was brief. In all but 6 instances the temperature reached normal on the 2nd day; in 5 cases on the 3rd day and in 1 case on the 4th day. With the subsidence of fever, symptoms disappeared and the patients rapidly returned to their customary states of activity and appetite. In general, the symptoms seemed to be somewhat proportionate to the febrile reaction but 2 of the individuals who had no febrile reaction were among those with most definite complaints. Patients with various degrees of illness, apart from fever, were divided in all

groups though a tendency to more pronounced symptomatology was observed in those with the larger doses of virus.

Antibody Titers—The serological responses measured by the inhibition of erythrocytic agglutination are shown in the tables and charts. In 26 of the 30 individuals a fourfold or greater rise in titer of antibodies was noted; two of the four failures occurred in the only 2 subjects with initial titers as high as 256. At the beginning of the experiment titers greater than 64 occurred in only 4 instances, while 2 weeks later only 2 individuals had titers as low as 64 (Chart 1). There was no discernible relation between the height of fever or the dosage of virus and antibody response. Those with normal temperatures and those with the milder degrees of fever after the weakest dose of virus responded equally as well as those who had the highest temperatures after the largest doses of virus. The mean titers before and after spraying were 48 and 1,516, respectively; in those receiving the unconcentrated virus; 46 and 1,581 in those receiving virus concentrated tenfold; 75 and 659 in those receiving the twice concentrated material. In 11 individuals with temperatures of 101° or less, the mean titer was 54 before spraying and 1,059 afterward, while the mean titers in 19 individuals with temperatures of 101.8 or greater were 56 and 1,336, before and after spraying, respectively.

The distribution of titers at the onset was scarcely diffuse enough to gain a satisfactory impression of relation be-

CHART 1

ANTIBODY TITERS BEFORE AND AFTER INHALATION OF TYPE B INFLUENZA VIRUS

tween antibody levels and clinical response. Moreover, three different concentrations of virus were employed. Nevertheless, all ranges of reaction were observed at any one initial level of antibodies (Chart 2). For example, of the 14 individuals with the lowest measured titer of less than 32, the recorded maximal temperatures varied from normal to 103.6°. Within the limited scale available the antibody level at the onset of the experiment appeared to have little relation to the extent of the fever which ensued.

Contacts—Among the 30 individuals selected as untreated controls, temperatures were not recorded but no recognizable signs of illness were noted. Nevertheless, serological studies revealed that 11 of them had developed in the period of 14 days an increase to at least four times the original antibody titer so as to indicate that infection had occurred. Three others had two-fold rises in titer (Table 2).

One physician who had watched the spraying procedure experienced generalized aching, pharyngeal irritation, nausea, and a temperature of 99.4° the day following exposure. He subsequently developed a high antibody titer.

The observations clearly indicate that the virus became distributed in the environment so that individuals occupying the quarters in which the spraying was done and mingling with subjects purposely given the spray, underwent in-

fection which was not detected by ordinary observation. Here again infection was not limited to contacts with the least antibody titers but was distributed over the range present in the control group.

SUMMARY

As a result of intranasal spray with influenza virus, Type B, a mild illness ensued. The disease was characterized by an incubation period of 10 to 24 hours; the onset was most commonly accompanied by chilly sensations, aching, loss of appetite, and nausea. The absence of respiratory symptoms or signs was notable. In one-fourth of the subjects the illness was sufficiently severe to put the individual to bed. Twenty-seven of 30 subjects had fever of 100° or greater in the first 24 hours; two-thirds had temperatures of 101° or higher. In the majority, signs and symptoms of illness had disappeared by the 2nd day after inoculation. The height of fever appeared to be more closely related to the amount of virus received than to any single level of antibodies present. All but 4 subjects had at least fourfold rises in antibody titer following the inhalation irrespective of the amount of virus received or the severity of the febrile reaction. Of 30 untreated controls, 11 developed significant serological changes indicating infection incurred while residing in the same quarters.

REINFECTION

In the latter part of March, 1943, 65 subjects on the same ward were available for study. Three groups were formed. The first consisted of 24 of the 30 subjects who had received virus in November. The second group comprised 10 individuals who had served as untreated controls in the first experiment and 13 new arrivals on the ward. A third group made up of 2 individuals previously sprayed, 9 of the earlier

controls, and 7 new arrivals, represented untreated controls. Temperatures were taken by mouth on the 2 days preceding the spray and subsequently by the rectal route. Efforts to gain information of clinical symptoms and signs were intensified. On March 29, 1943, each of the 47 individuals in the first two groups received an intranasal spray of the Lee strain of Type B influenza virus, concentrated tenfold, for 5 minutes.

Clinical Response—Symptoms and fever first occurred within 12 hours of the exposure and in 24 hours the effect was at its height. Essentially the same symptoms were noted by those given virus the second time and by controls receiving their first inoculation. They were most prominent again in individuals with highest fevers.

	<i>Resprayed</i>	<i>Sprayed Controls</i>
Chilly	8	7
In bed	4	8
Headache	4	7
Malaise	3	2
Anorexia	2	3
Cough	2	2
Bodily aches	1	3
Nausea	1	2
Dizzy	0	3
Sore Throat	0	3
Runny Nose	0	1
Vomiting	0	1

Thirteen of the reinoculated and 14 of the sprayed controls had definite symptoms; 4 and 8, respectively, were in bed. In most instances the illness subsided 24 to 36 hours after inhalation, but in a few cases temperatures remained elevated until the 3rd day.

Among the 24 individuals tested for immunity by reinoculation of virus, 21 developed temperatures of 100° or higher, as did all 23 of those sprayed for the first time. However, 19 (82.6 per cent) of the latter developed fever of 101° or greater while only 9 (37.5 per cent) of the reinoculated group reached that level (Table 3, Chart 2). The rapidity with which fever developed

and declined was essentially the same in both groups.

No sharp change in the leukocyte count occurred. The mean count of individuals before spraying was 12,300 and on the 1st and 2nd days after spraying was 11,300 and 8,900, respectively. No difference was observed in the trends exhibited by those receiving a first or second inhalation of the virus.

It becomes quite evident that 4 months after infection with influenza virus, Type B, inhalation of the same virus induced in the same group of individuals illness clinically similar to that which followed the first exposure. The majority of those retested had lower temperatures and symptoms were generally less pronounced than in control subjects receiving their first inhalation of virus.

Serological Response—Prior to the

original spraying of the group the titers of antibody to influenza virus, Type B, were preponderantly low. In consequence of that experience, much higher levels were reached and, to a great extent, maintained through the interval of 3½ months between the termination of the first study period and the beginning of the second. Moderate shifts occurred, however. In 8 instances the titers decreased within a range which might be anticipated with the lapse of time. Increases which were noted in 12 instances are probably attributable to continued accessions of antibody beyond the time at which the second sample was obtained rather than to deterioration of the earlier samples of serum during the period of storage. This was evidenced by comparing results of tests conducted in December with the first two specimens of serum

and those in April which involved all four specimens.

Except for one value of 16,000 the titers of the group immediately before reinoculation ranged evenly from 128 to 2,048 with a mean of 848 and a median of 512. The titers of the con-

Symptoms: 0 to +++ = increasing severity of constitutional reaction

Antibody titers: Numerator = titer before inoculation.
Denominator = titer after inoculation.

Following the inhalation of virus, 8 of the experienced and 15 of the new subjects developed significant increases in titer. The increment of increase, however, was much greater in the controls whose mean titer rose from 141 to 1,260 (median 512) while the rise in resprayed individuals was from a mean titer of 848 to one of 1,776 (median 1,024). Significant serological responses in both groups were most common in those with the lower antibody levels and least frequent in subjects with high titers.

COMPARISON OF RESPONSE OF SAME INDIVIDUALS TO FIRST AND SECOND EXPOSURES

Fever—Of the 24 individuals who received the two inhalations of virus, 21 developed fever of 100° or more

each time; only 1 remained below that point in both tests. In 10 instances the maximal temperature following the second exposure was within 0.5° F. of the height reached in the primary attack; the majority of these individuals were those who, following the smaller amounts of virus, had the milder fevers originally (Chart 4). One of them, however, with fever of 103.4° in the primary episode responded with 103.8° to the second inoculation (Chart 5). On the other hand, of the 14 cases who exhibited fever higher than 101° on the first exposure, 10 showed decidedly lower temperatures, with a mean decline of 1.5° F., in the second test (Chart 6). In only 3 instances was the second fever significantly higher than the first (Chart 3, Table 6).

CHART 3

COMPARISON OF FEBRILE RESPONSE OF SAME INDIVIDUALS TO SUCCESSIVE INHALATIONS OF INFLUENZA B

Two interpretations are suggested by the results. The fact that primarily those with the highest original fevers exhibited reduced temperatures following reinoculation (Chart 4) might be considered to indicate that they alone had profited from the earlier experience and that the reactive state of the remaining individuals had been essentially unaltered. Since, however, most of the subjects with fever of about the same extent in both tests were those who received the smaller doses of virus the first time, it may be inferred that the milder response to the first inhalation of virus had been just as beneficial in

CHART 4—Subjects 4 and 6 received unconcentrated virus in November. Temperature was low, no symptoms were noted but sharp rises in antibody occurred. Four months later virus concentrated tenfold was administered. The second clinical response was similar to the first but no further increase in antibodies took place.

The left half of each chart represents the original febrile response beginning the day after inoculation; the right half the response to reinoculation. The vertical columns indicate antibody titers immediately before and 2 weeks after inoculation. Symbols in upper right corners indicate severity of symptoms. (See Table 6). *M* signifies oral temperatures.

CHART 5—Illness was among the most marked of the group after each exposure to virus concentrated tenfold. Significant antibody increases occurred both times (Subject 29).

CHART 6—The charts of subjects 22 and 23, who had sharp febrile reactions, pronounced symptoms, and significant antibody responses to the first inhalation of virus on November 28, 1942. Second inoculation on March 29, 1943, was followed by markedly reduced temperatures and symptomatology.

limiting the second response of these individuals as was the more severe reaction in reducing the height of fever in the other group. Had this not been the case higher temperatures, equivalent to those of the controls, might have occurred (Chart 3).

Symptoms—Although the symptomatic evidence is of limited value, definite complaints were obtained from 14 of the group after the first spray and from 13 of them following the second. A comparison of the complaints of the same individuals in the two experiences revealed the following:

No symptoms either test.....	4
Decreased severity in second test.....	6
Increased severity in second test.....	5
Same severity both tests.....	6
No information either test.....	3

In both periods symptoms tended to

be most severe among those with the highest fevers. In the individuals exhibiting the more marked symptoms after the second exposure, however, only 1 showed higher fever than in the original test. Diminished febrile reactions to the second spray, therefore, were not consistently accompanied by a reduction in symptoms, nor was the reaction to reinoculation clearly referable to the severity of initial response. The more marked symptoms in the second test followed just as commonly after a severe as after a mild primary response (Table 6).

Serology—The individuals subjected to reinoculation had considerably higher titers of antibody at that time than were observed at the time of their original inoculation. In general, they were less responsive, serologically, to

the second inhalation than to the first. The mean titers before and after the first exposure were 65 and 1,180; before and after the second, 848 and 1,776. Whereas, originally 20 of the 24 had antibody rises to four times or more the initial titer, and 2, twofold; after the second spray 7 showed twofold increases and only 8 had a fourfold or greater increase (Tables 5 and 6, Chart 1). Although these 8 individuals had exhibited significant responses to the first inoculation, the medians of their titers preceding and following the first infection were low, 16 and 96, respectively. At the time of the immunity test, 5 of them had titers of 128; the lowest level encountered in the retested series. It is well to emphasize

that they belonged to the group with most definite symptoms and fever in each test. Despite the sharp rise in antibodies from the original level these subjects were again clearly susceptible to reinoculation with serological and clinical responses to second inoculation in many respects parallel to the first.

Briefly, inhalation of Type B influenza virus 4 months after exposure to the same virus induced again febrile response in the majority of the group. In general, temperatures were either lower or about the same level as those exhibited in the first attack. When symptoms could be obtained there was no relation demonstrable between their severity in the first instance and the response to the second attack (Chart 7).

CHART 7.—Subject 9. Illustrates the presence of pronounced symptoms and sharp antibody response with minimal febrile reaction following inhalation of unconcentrated virus. Test for immunity with concentrated virus elicited no symptoms, slight fever and no further rise in antibody.

Subject 11. Despite well marked fever, symptoms and antibody response to the first inoculation, the severity of the second clinical reaction was undiminished. The antibody titer was not significantly affected.

Although antibody titers were decidedly higher at the time of reëxposure than originally, one-third of the subjects, comprising largely those with the most severe second illness, responded with significant serological reactions again. The major effect of previous infection appeared, therefore, to be a reduction in severity of the second attack.

PERSISTENCE OF VIRUS

No virus was recovered from the throat washings obtained from 29 sprayed subjects 24 hours after inhalation of the virus. Each specimen was tested in mice with the appearance of pulmonary lesions taken to indicate infection. With five specimens attempts were made to adsorb virus from the washings with chicken erythrocytes and concentrate it by elution. No significant agglutination of red cells by the eluate was noted. The failure to find virus under these conditions was somewhat surprising in view of the short period elapsing after the spray.

On the other hand, that virus was in the air was demonstrated by the infection of mice exposed during the spraying procedure. The 5 mice which were given a stimulating intranasal inoculation of broth following exposure in the spray room, died of influenza virus infection; 2 of the remaining 5 died and the other had extensive pulmonary lesions when autopsied on the 10th day. All the mice exposed in the large day room occupied by the patients survived for the 10 day period of observation but had extensive pulmonary lesions. Influenza virus, Type B, was identified. These results show that the virus was distributed in the atmosphere by the spray itself and probably for a limited period, at least, by the infected subjects. It is of interest, however, that in this second series only 2 of the 18 contact controls gave serological evidence of having been infected through the environment in contrast to 11

instances in the first contact group.

RELATION OF CLINICAL RESPONSE TO SEROLOGICAL STATUS

In the first experiment, the use of three different strengths of virus apparently accounted for certain variations in clinical response. Partly because of these conditions, no intimate relation between symptoms or fever and the initial or subsequent antibody titer was evident. For the second spraying, virus concentrated tenfold was used throughout and the influence of other factors can be considered on the basis of uniform dosage.

In Chart 2 and Table 8 it is seen that when compared with themselves in the first test or with the controls for the second test, individuals undergoing their second experience had in general the higher antibody titers and lower temperatures. Moreover, the controls with lowest antibody titers presented a preponderance of high temperatures. In the intermediate range of titers (128-256) both controls and reinoculated subjects were found. The temperatures of individuals in this antibody zone were more widely distributed than those in the higher or lower antibody levels. But because of the limited numbers and since practically all the titers above 256 belong to individuals previously inoculated while the low titers of 64 or less are limited to those who had not undergone recent infection, no strict conclusion can be drawn. Nevertheless, a comparison of the responses of the resprayed and the controls of the second series does suggest a trend of decreasing severity of fever as antibody levels rise. Only 4 of the 24 reëxposed subjects had temperatures of 102° or more, while 14 of the 23 controls reached that level. Totaling all groups it is seen that temperatures of 101° or more occurred in 22 of the 32 (68.7 per cent) with titers of 64 or less, in 16 of 23 (69.5 per cent)

TABLE 8

Relation of Febrile Response to Influenza B and Antibody Titer

with titers of 128 and 256, in 4 of 16 (25 per cent) with titers of 512 or more.

The tendency for symptoms to be proportionate to fever was noted in both periods of observation of the original group and in the sprayed controls. At the time of the respraying, 9 of the 13 reinoculated subjects who presented positive signs or symptoms resided in the antibody levels of 128 or 256, the lowest of the group. This suggests again an association between antibody titers and severity of disease.

The 9 reinoculated individuals (2, 8, 11, 12, 13, 14, 25, 26, 29) with most definite symptoms (++ or ++++) included 7 of the 9 with fever of 101° or greater, 7 of the 9 with lowest antibody titers (128 or 256), and among this 7 were 6 of the 8 who showed a fourfold or greater rise in antibodies following the second inoculation. In these instances, involving individuals with the lowest titers of the group, fever, symptoms, and antibody response combined to give the most complete evidence of infection (Chart 5). Of the 8 reinoculated subjects without complaints only 1 had fever as high as 101°, their antibody titers were all 512 or greater, and none showed a significant increase in antibodies. The suggestion arises that under the conditions of the present experiment significant rises in antibody are most common in those with the most definite clinical signs of disease. On the other hand,

the absence of a fourfold increase in antibodies cannot be interpreted as freedom from infection when fever occurs in the presence of high antibody titers since they are less readily affected by additional antigenic stimuli (Chart 7, subject 11).

Among the sprayed controls a broad relation was also found between height of fever and the extent of antibody response. Of 10 with temperatures greater than 102°, all but 1 showed a fourfold or higher rise in antibody and 6 had more than an eightfold increase; of 13 with 102° or less only 6 had an increase of fourfold or more and none had more than eightfold increase. It should be recalled, however, that no such correlation was found in the original group receiving the different doses of virus.

In summary, the relation between the height of circulating antibodies and clinical response to infection is not clearly demonstrable in the limited data available from the present study. There exists a tendency, most evident in the previously infected, for high antibody titers to be associated with the lower temperatures. Among the controls sprayed in the second experiment there was also a tendency toward an inverse relation between the severity of reaction and the level of circulating antibody. On the other hand, all degrees of reaction were found at any given antibody level.

The results among the reinoculated individuals and their controls at the time suggest that the most prominent serological responses to infection occur in subjects with the most marked clinical reaction, although this was not noted among the individuals sprayed with different doses of virus in the first experiment. The fact remains that despite a rather uniform increase in antibody to levels beyond those encountered in the group originally, reinoculation 4 months later caused clinical evidence of infection in a high proportion of the 24 subjects a second time and in 8 individuals a second significant increase in antibody titer took place.

SPECIFICITY OF FEBRILE REACTIONS

Since the great majority of subjects in all three sprayed series, irrespective of dose or experience, had fever of 100° or more, it is apparent that if the lower fevers represent disease, infection 4 months earlier did not prevent reinfection. Although the serological responses and the presence of symptoms in afebrile subjects indicate that the mild fevers were associated with infection, the possibility that certain of the lower temperatures in the reinoculated group might be nonspecific remained. In order to study the question a series of individuals were sprayed with virus inactivated by ultra-violet irradiation.

Concentrated virus of the same lot as that used in the second test was irradiated with ultra-violet light for sufficient time to inactivate the virus as measured by loss of infectivity for mice and chick embryos. Eight subjects not previously studied and 4 who had been sprayed with active virus 4 months earlier were then given inhalations of the inactive virus for 5 minutes. Temperatures were taken before and after spraying and serological tests were made with serum obtained before and 2 weeks after the inhalation. One of the previously untreated subjects developed

chilly sensations and a temperature of 102° the following day but an antibody titer of 32 remained unchanged. It seems likely that this represented an incidental illness. One of the 4 individuals sprayed earlier with active virus had a temperature of 100.4° on the 3rd day after spraying. The tardiness of this fever in comparison with the rapidity with which fever follows active virus indicates that it was not of the same nature. No other reactions were observed. None of the individuals showed a fourfold rise of antibodies as a result of spraying with inactivated virus.

The evidence clearly indicates that the elevated temperatures observed in the studies with active virus are not related to nonspecific factors associated with the spraying and that allergic reactions to egg fluid or the virus played no rôle in the symptomatic or febrile responses to the inhalation of active virus. Subsequent studies have added ample confirmation of this conclusion.

DISCUSSION

The inhalation of nebulized influenza virus, Type B, by human subjects produced an illness closely resembling that seen in the milder outbreaks of the natural disease. The course of the disease was brief and the severity varied among individuals, depending to some extent upon the concentration of virus administered. It is noteworthy that in most instances the incubation period was 12 to 24 hours, that temperatures greater than 102° F. were common, and that respiratory signs and symptoms were conspicuously infrequent while constitutional symptoms were predominant. No complications ensued.

Four months after the induction of clinical influenza, reëxposure of the same group of individuals to the same virus was again followed by clinical disease evidenced in fever, symptoms, and

serological reactions. Nine of them had temperatures of 101° or greater and 8 exhibited a second significant rise in antibodies. That a state of increased resistance had persisted over this period was seen, however, by the reduced severity of the second response in comparison with the primary reactions of the same subjects or controls. In estimating the degree of resistance, the significance of the febrile reactions among the reinoculated individuals must be appraised. The milder febrile reactions in the original group were largely limited to those receiving the smaller concentrations of virus. In the second instance, where one preparation of virus was used throughout, they were essentially exhibited by the reinoculated subjects in contrast to the inoculated controls. The infrequent and irrelevant fevers in untreated controls and in those sprayed with inactive virus strongly suggest that the temperatures of 100° to 100.9° in the reinoculated subjects represent, in the main, reactions to the inhalation of active virus rather than allergic or nonspecific responses to the sprayed material. This is further supported by the presence, as in subjects 12, 14, and 21, of symptoms and further increases in antibody titer comparable to those of individuals with higher fevers. Hence, it must be concluded that few of the previously infected subjects were wholly refractory to reinfection. On the other hand, the fact that 15 of the 24 reinoculated had temperatures below 101° while 19 of the 23 controls had temperatures of 101° or more indicates that the earlier infection had conferred a significant degree of resistance upon a majority of the individuals involved. Had the infection been milder the effect would probably have been enhanced, but this would require the employment of much larger numbers of individuals than seems feasible at the present time.

Information as to the influence of

circulating antibodies upon the response to infection is not readily drawn from the present data. Combining the results from all groups it was found that 69 per cent of those with titers below 512, and 16 per cent of those with titers of 512 or more developed temperatures of 101° or higher. However, the low titers of antibody were preponderant among those receiving their first inoculation while those who had been previously infected possessed uniformly the higher titers. The recently experienced subjects with high titers had, in general, lesser febrile reactions than the inexperienced with low titers. On the other hand, the persistence of an increased titer of circulating antibodies from the first infection did not necessarily prevent the development of clinical disease a second time. Thus, although resistance and circulating antibodies were enhanced by infection, the evidence does not permit any conclusion as to a causal relationship. As has been shown elsewhere, an increase in circulating antibodies following infection⁵ or vaccination⁶ results in an increased neutralizing capacity of the nasal secretions. In these terms, circulating antibodies serve more as an index of the activity of the local protective mechanisms than representing the actual agency of resistance. This concept would appear clearly applicable under the conditions of the present study.

It may be objected that the procedures adopted constitute too severe a test of the immune state and that the respiratory tract is much more intensely exposed to the virus than is the case in natural infection. This implies that under natural conditions a minute amount of virus enters the upper respiratory tract during a brief period of exposure. On the other hand, recent studies of air-borne infection call attention to the fact that, in closed spaces, contamination of the air by infected individuals constitutes an opportunity

for prolonged exposure and permeation of the respiratory tract with much larger amounts of virus than mere contact would afford. The serological evidence among 11 of 30 contact controls in the first experiment demonstrates that the virus employed in the present investigation also produced infection after entering the respiratory tract by the more physiological method of normal respiration in an infected atmosphere. Although approximately 0.5 ml. of the virus was delivered to each individual the actual amount retained is not known because much of it was promptly exhaled. Moreover, the differences in response among the groups receiving different concentrations of virus suggests that the amount was not greatly in excess of that needed for adequate clinical reaction. The frequency of infection was clearly heightened by the manner of observation, detecting brief and mild responses which under conditions of normal activity would not have been noted. The incidence of clinical disease in an epidemic is related to the care with which a population is observed and the infectiousness of the prevalent strain. The fact that the incidence of influenza, Type B, has been low in recent epidemics may well reflect a need for relatively large doses of the current strains in order to produce the disease naturally as well as experimentally. For the purposes of this investigation it has been advantageous to employ amounts of virus sufficient to compensate for natural defects in the strain and yet to permit a demonstration of the differences in response of individual subjects. Under other conditions the same procedures have clearly demonstrated firm immunity in groups under investigation.

Bull and Burnet⁷ have recently reported observations concerning the immune response of human subjects to small intranasal doses of an attenuated form of the same strain of influenza

virus, Type B, as was used in these studies. It is of interest to point out certain differences in effect and interpretation. Their subjects were selected because of low antibody titers, and the presence of immunity was, to a large extent, determined by failure to show a rise in antibodies to the second inoculation. The demonstration of virus in nasal secretions was also involved. The symptoms were extremely mild and mostly nasal; fever is not recorded. Certain of the rises in antibody to which they ascribe importance, seem of doubtful significance; an increase in antibody after reinoculation may not occur even with sharp clinical response. The predominance of nasal symptomatology in their cases as evidence of response is in contrast to its relative infrequency in the clinical disease. The absence of controls for the immunity test and for the nasal symptoms furnishes little basis for evaluating the results. Certainly, there is no evidence in our studies that subjects with highest antibodies respond with most marked symptoms; quite the contrary. Moreover, if frank infection fails to give uniform staunch resistance over a period of 4 months, it seems unlikely that single exposure to a much milder single stimulus by the same route will have a greater effect. Bull and Burnet have measured essentially the serological reactions to a mild application of attenuated virus and it seems doubtful that further inference of its effect upon resistance to clinical infection can be drawn at present.

From the studies here reported the suggestion is derived that if procedures devised for prophylaxis against influenza are to be effective they should be repeated at intervals shorter than 4 months. The evidence shows that the degree of resistance persisting 4 months after infection is less influenced by the severity of the original infection than by the responsiveness and con-

tinued activity of the individual's immune mechanisms, suggesting that selection may be made of those most in need of the additional stimuli.

SUMMARY

Inhalation of finely dispersed Type B influenza virus by human subjects resulted in a high incidence of clinical infection resembling a mild form of the natural disease.

Four months later 24 of the same subjects received a second inhalation of the same virus. Fever, symptoms and serological responses were noted a second time. The illness was milder in the majority of previously infected individuals than in controls inoculated at the same time. Few were refractory to reinoculation.

The diminished response to reinfection was most evident in those who had the highest fevers in the first test. Nevertheless, the evidence indicates that mild primary infections were as beneficial as the more severe ones.

Although there was a trend toward association between high antibody titers and low temperatures, no uniform correlation between the antibody titer of an individual and his response to inoculation was found.

Epidemiology of Atypical Pneumonia and Acute Respiratory Disease at Fort Bragg, North Carolina*

Commission on Acute Respiratory Diseases,† Fort Bragg, North Carolina

DURING the past decade atypical pneumonia has been recognized with increasing frequency both in the armed forces and in civilian groups.¹⁻⁴ The disease is a clinical syndrome which is similar in onset and symptomatology to moderately severe acute respiratory diseases, such as nasopharyngitis, bronchitis and gripe. The characteristic feature of the disease is the finding of a pulmonary lesion on roentgenographic examination in the absence of rigor, pleuritic pain, rusty sputum, and other signs which are usually associated with acute bacterial pneumonia. In fact, extensive radiographic shadows may be present without being evident by physical examination of the patient. Therefore, the frequency with which this syndrome is diagnosed depends upon the number and frequency with which routine roentgenograms of the chest are taken on patients with acute respiratory illnesses.

The incidence of the disease in the Army is high in relation to other forms of pneumonia. In certain Army camps where routine radiographic studies were made on all respiratory admissions and where careful bacteriological studies were done, it was found that from 85

to 90 per cent of all cases of pneumonia were of the atypical variety.^{5, 6}

The etiology of the disease is unknown. Although a number of agents, viruses, rickettsiae, fungi, and bacteria have been shown to produce similar clinical syndromes,^{7, 8} these agents have been thoroughly excluded as possible causes in the great majority of cases.^{5, 6} Since there is a close clinical similarity between atypical pneumonia and common respiratory disease, the epidemiological studies in the present paper include a consideration of both diseases. Special emphasis has been placed upon studies of the incidence of respiratory diseases among seasoned men and new recruits, and upon the epidemiological relationship between atypical pneumonia and other acute respiratory infections. A brief description of an epidemic of German measles will also be presented for the purpose of contrast to the other findings.

The period of this study extends from October 31, 1942, to May 28, 1943. During this interval, the reported admission rates for common respiratory disease were similar to comparable rates for all troops in the Fourth Service Command and for the Army in the Continental United States. Moderate numbers of cases of meningococcal meningitis, streptococcal pharyngitis, and pneumococcal pneumonia occurred; but the total of all cases of known etiology was small in comparison with the total incidence of respiratory dis-

ease. The great majority of the cases were undifferentiated respiratory infections of unknown etiology.

METHODS

The data on atypical pneumonia and German measles have been obtained by abstracting the records of the Registrar's Office, Station Hospital, Fort Bragg. The final diagnoses of the hospital staff on disposition of the cases have been accepted. Throughout the period of this study, the medical staff was searching for cases of atypical pneumonia. Frequent roentgenograms were taken on cases of respiratory disease in which this syndrome was suspected. The data on incidence of acute respiratory dis-

eases have been obtained by tabulating the daily numbers of admissions to the respiratory wards of the hospital. The diagnoses in these cases are based upon the impression of the medical officers in the admitting office. A separation of these respiratory admissions into diagnostic groups has not been attempted.

Fort Bragg is a large army post situated in southeastern North Carolina. Among the various organizations stationed there, the one which has been studied in greatest detail is the Field Artillery Replacement Training Center (FA RTC). This organization is a school which gives basic training to new recruits. The trainees come directly from reception centers in all parts of the

RESPIRATORY ADMISSIONS

FIGURE 1—Incidence rates of respiratory admissions per 1,000 per week, FA RTC and other organizations stationed at Fort Bragg, N. C., October 31, 1942, to May 28, 1943

United States. The largest proportion, however, come from the northeastern states. With few exceptions, the men have had less than 1 month of military experience prior to their arrival, and the majority of them have been in the Army less than 10 days. At the time of their arrival, most of the recruits are grouped into battalions of approximately 1,000 men each, and are further subdivided into four batteries of 250 men each.

During the period of the present study, two separate courses of basic training were given in different battalions. One course, designed for limited service men, lasted 8 weeks. The other, designed for field artillery trainees, was of 13 weeks' duration. After completion of training, the men were transferred to other stations. Thus,

there was an intermittent flow of large groups of new recruits through this center.

The other organizations on the post were tactical and service units which were composed largely of seasoned men with 3 to 6 months or more of military experience. Some of these organizations received complements of new recruits from time to time, but the size of such additions was small in comparison with the total strength of the units.

All soldiers at Fort Bragg were housed in standard two-story barracks originally designed for 63 men. Crowding in the barracks occurred in some organizations but this rarely exceeded 80 men per barrack. In the FA RTC, only occasionally were more than 70 men housed together in one building.

INCIDENCE OF RESPIRATORY ADMISSIONS
AMONG NEW RECRUITS AND
SEASONED MEN

The weekly incidence rates of respiratory admissions from the FA RTC and from the other organizations stationed at Fort Bragg are shown in Table 1 and Figure 1. In the FA RTC, the incidence began to increase in November and rose sharply to a peak of 36 cases per 1,000 per week in the last week of December. The rates fell abruptly during January, but rose again in February and reached a somewhat lower but broader peak in March. There was a continuous downward trend in April and May. The two peaks in this curve developed immediately following the ar-

rival of large groups of several thousand new recruits.

The incidence rates for the other organizations on the post were markedly and consistently lower than the rates for FA RTC. They increased slowly through November and December, and reached a peak of only 8.4 per 1,000 per week in the middle of January, after which there was a progressive downward trend. Throughout the winter, the incidence in the FA RTC was from two to ten times as high as that in the other organizations. As will be shown later, this difference is clearly the result of the high proportion of new recruits in the FA RTC.

admissions in the battalions of the FA RTC revealed that the high rates occurred almost entirely during the first 4 weeks following the arrival of the trainees. A definite and rather characteristic epidemic of respiratory disease occurred in each battalion of new recruits which arrived between December 1 and April 10. The data on several of these battalions will be presented.

The incidence rates in the four bat-

teries of "Z" battalion are shown in Table 2 and Figure 2. The men in this unit arrived between December 10 and 13. During the first week following arrival, the incidence rate was 50 per 1,000 per week. It increased moderately in the second week, and markedly in the third week, after which it fell abruptly. During the 8 week course of training, over 30 per cent of the entire group were admitted to the

hospital for respiratory disease, and 86 per cent of the cases occurred within the first 4 weeks.

In Table 3 and Figure 3, are presented the data on Battalion "Y" over a period of 4 months. In this battalion, three batteries of new recruits arrived during the week from December 26 to January 2. An epidemic of respiratory disease occurred during the following

month. At the end of January, the fourth battery was filled with new recruits and a sharp increase in incidence occurred among them. The men in the first three batteries completed their training late in February and were transferred to other stations. New groups of recruits were assigned and an epidemic of respiratory disease occurred immediately following their arrival.

An unusual situation obtained in Battalion "X" (Table 4). Approximately half of the men in this battalion came directly from reception centers, as in the other battalions, but the other half of the men came from a camp where they had been resident for a period of from 6 weeks to 3 months. This group, therefore, was not under observation during the apparently critical first month of army life. The data for this battalion have been grouped according to the length of service of the men prior to arrival at Fort Bragg. The men who had been in the Army less than 1 month experienced moderately high admission rates for respiratory disease, while among those who had had more than 1 month of army service, the incidence of respiratory admissions was negligible.

RELATIONSHIP OF ATYPICAL PNEUMONIA TO RESPIRATORY ADMISSIONS

There was an apparently constant relationship between the incidence of respiratory admissions and atypical pneumonia both in the FA RTC and in the other organizations on the post (Table 1, Figure 4). Throughout the period studied there is a rough parallelism between the incidence curves of the two diseases. In spite of marked differences between the total respiratory admission rates in the FA RTC and the other organizations, the ratio of respiratory admissions to atypical pneumonia was approximately 10 to 1 in both groups.

This relationship was maintained within the battalions of the FA RTC. In Table 5 and Figure 5, data are shown for four battalions according to

TABLE 6

† Rates expressed as cases per 1,000 per week

FIGURE 6—Incidence of respiratory admissions and atypical pneumonia among 14 battalions, FA RTC, according to 7 day periods following arrival at Fort Bragg, N. C., December, 1942, to May, 1943

7 day periods following arrival. These particular battalions have been selected from a group of 14 similar instances. They have been picked as representative examples to show the variations as well as the typical picture.

In 10 of the 14 groups, the peak incidence of atypical pneumonia coincided with that of respiratory admissions. Three examples, Battalions "U," "W," and "Z," are shown in Figure 5. In two of the remaining four battalions, the peak incidence of atypical pneumonia preceded that of the respiratory admissions as in Battalion "V"; and in two, the cases of atypical pneumonia were scattered without definite peaking.

Since the total number of cases of

atypical pneumonia in each battalion was small, considerable chance variation might be expected. In order to reduce this variation resulting from small numbers, the data from 14 battalions have been consolidated according to time of arrival. The results are shown in Table 6 and Figure 6. The incidence, both respiratory disease and atypical pneumonia, was clearly concentrated during the first 4 weeks following the arrival of the men, after which the incidence was of the same order of magnitude as that among seasoned men.

CONTRAST BETWEEN GERMAN MEASLES AND RESPIRATORY ADMISSIONS

The occurrence of an epidemic of

German measles during the late winter and early spring of 1943 provided an opportunity for contrasting the distribution of a known specific infection with that of atypical pneumonia and respiratory disease. Scattered cases of German measles appeared in the FA RTC during January and February. The incidence rate increased rapidly and reached a peak of 6.7 per 1,000 per week in the week ending March 26. The rate dropped to 2.5 in the following week and progressively declined thereafter.

During the period of the German measles epidemic, 9 separate groups

of new recruits were under observation. In 7 of these 9 groups, the peak incidence of German measles occurred during the week ending March 26. In one group, an equal number of cases occurred during the week ending March 19 and March 26, and in only one group did the highest incidence of this disease occur early in March.

In Figure 7, the time of occurrence of German measles is contrasted to that of the epidemic of respiratory disease in 5 representative battalions. The cases of German measles were clearly concentrated during the month of March. This concentration appeared

FIGURE 7—Incidence of respiratory admissions and German measles, 5 representative battalions, FA RTC, Fort Bragg, N. C., January 22 to April 30, 1943

to be unrelated to the time of arrival of the recruits. These findings stand in striking contrast to the epidemics of respiratory disease and atypical pneumonia, which occurred in each month from December to April and were directly related in every instance to the time of arrival of the men.

DISCUSSION AND SUMMARY

This study has served to emphasize the marked difference in incidence of respiratory disease between new recruits and seasoned soldiers. This phenomenon is well recognized in the Army.⁹ Similar occurrences have also been described in certain civilian groups, particularly in schools.¹⁰ The mechanism of this phenomenon cannot be explained adequately on the basis of present knowledge. Presumably, when large groups of individuals are brought together into a new environment, conditions become favorable for the development or spread of respiratory disease. In the absence of knowledge of the etiology of this group of diseases, it is impossible to determine whether the high incidence results from the interchange of numerous separate specific agents among individuals in close contact or whether the change in mode of living results, in some obscure fashion, in a breaking down of immunity or resistance to a common, single, specific agent.

It seems probable that both factors play a rôle in the phenomenon. It is recognized, for example, that certain diseases of known etiology, such as meningococcal meningitis and pneumococcal pneumonia, occur most frequently among new recruits.^{9, 11} It is not clearly established, however, what part a preceding acute respiratory infection may play in the pathogenesis of these bacterial diseases. The one factor which is evident from the present studies is that during the past winter at Fort Bragg, the first 4 weeks of army life was a critical period, and that

after the first 4 weeks, soldiers appeared to have an increased resistance to respiratory diseases.

The observations on atypical pneumonia indicate a close epidemiological association between this syndrome and common respiratory disease. Atypical pneumonia was continuously present at Fort Bragg throughout the period studied. The 10 to 1 ratio of respiratory admissions to cases of atypical pneumonia was maintained with reasonable constancy both among new recruits suffering a high incidence of respiratory disease and among seasoned men in whom the incidence was low. Taking this evidence in conjunction with the clinical similarity between the two diseases, the hypothesis is suggested that atypical pneumonia may be a severe manifestation of the same specific infection or infections which produce common respiratory illnesses. Reimann¹² and others^{13, 14} have also advanced similar theories. Proof of such hypotheses, however, must rest upon demonstration of the etiological agent.

Captain D. L. Martin, M.A.C., Registrar, Station Hospitals

Primary Atypical Pneumonia*

Commission on Acute Respiratory Diseases,† Fort Bragg, North Carolina

DURING recent years a rather characteristic syndrome in the group of respiratory diseases has been recognized with increasing frequency. This syndrome has been referred to by a variety of names, among them such terms as "atypical bronchopneumonia,"¹ "acute influenza pneumonitis,"² bronchopneumonia, variety X,³ acute pneumonitis,⁴⁻⁶ and disseminated focal pneumonia.⁷ Loosely, and quite improperly in the light of our present knowledge, the infection has also been called "virus" pneumonia.⁸

Present evidence indicates that this syndrome has a diverse etiology. In the great majority of the cases, however, the cause cannot be demonstrated, but the illness is clinically similar to or indistinguishable from that due to known agents. The basis of discussion here will be those cases of unknown cause, officially designated by the Army as primary atypical pneumonia, etiology unknown.⁹

CLINICAL ASPECTS

The clinical characteristics of primary atypical pneumonia^{8, 10-12} are those of an acute infection of gradual onset in which constitutional symptoms, such as headache, fever, malaise, and chilliness,

predominate over respiratory symptoms in the early stages. A dry, irritating cough, sometimes paroxysmal in nature, develops soon after onset and may be accompanied by substernal discomfort, but rarely by true pleural pain. As the disease progresses, the cough becomes productive of mucus and of purulent or, occasionally, blood-streaked sputum. The typical bloody or "prune-juice" sputum of pneumococcal pneumonia does not occur. Coryza, sore throat, and gastrointestinal symptoms may be observed. The illness is ordinarily of mild or moderate severity and the patient does not appear as sick as his complaints would suggest. In a small proportion of the cases prostration, dyspnea, cyanosis, and circulatory collapse may occur, but this is not the common finding.

Physical examination in the early stages ordinarily reveals a moderately ill patient with a mild inflammatory reaction of the upper respiratory passages. The remainder of the examination usually reveals no abnormal findings. The leukocyte count is normal. Up to this point, then, there is little in the history or physical findings to suggest a diagnosis of primary atypical pneumonia rather than one of ordinary undifferentiated acute respiratory disease. The one objective criterion which most authorities require to establish the diagnosis of primary atypical pneumonia is the presence of a pulmonary shadow or lesion by roentgenogram.¹³⁻²⁰ In a large proportion of the patients such a lesion is demonstrable radiographically.

* Presented by John H. Dingle, M.D., before the Health Officers Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

† Members of the Commission are Drs. John H. Dingle, Director, T. J. Abernethy, G. F. Badger, J. W. Beard, N. L. Cressy, Major, M.C., A. D. Langmuir, C. H. Rammelkamp, J. M. Rueggeger (resigned), and E. Strauss, 1st Lt., M.C.

early in the illness, before the appearance of associated physical signs. The infiltration commonly begins in the perihilar region and spreads in a wedge- or fan-shaped fashion toward the periphery of the lung field. It appears soft and either patchy or homogeneous in character. It may have an appearance suggesting atelectasis.²¹ The process most often involves the lower lobe, but may affect any lobe or combination of lobes.

As the disease progresses, it is accompanied by a remittent fever which varies between 99° and 104° F., persists for approximately 3 to 8 days, and terminates by lysis. The pulse and respiratory rates are relatively low during the febrile period. Rather late in the disease characteristic subcrepitant

"sticky" moist rales appear over the area of infiltration. They are best elicited after cough and deep breathing, and usually persist for days or weeks even after the pulmonary fields have cleared roentgenographically. Signs of definite consolidation are usually lacking. Convalescence is ordinarily prolonged but uneventful, and recovery is the rule (Figures 1, 2, 3).

The above description characterizes the usual case of primary atypical pneumonia. Variations in this picture, however, are extreme. "Unrecognized" cases have been detected by routine radiographic examination of soldiers on active duty. These cases have definite pulmonary lesions associated with minimal subjective or other objective evidences of infection. An estimate of

FIGURE 1—Clinical chart of patient with atypical pneumonia (mild infection)

FIGURE 2—Clinical chart of a patient with moderately severe atypical pneumonia. Patient recovered after prolonged convalescence.

(Published in *War Med.*, 3:223, 1943.)

the frequency of occurrence of these cases is shown by the following figures:

In a group of 2,814 radiologic examinations for officers' candidate school at Fort Bragg, 12 cases of primary atypical pneumonia were discovered, indicating a prevalence rate among apparently "normal" soldiers of about 0.4 per cent (Figure 4). Relapses or recurrences of infection are not unusual during the course. Rarely the moderately severe or severe illness may be complicated by secondary bacterial infection, pleural effusion, bronchiectasis, or signs suggestive of involvement of the central nervous system. A fatal outcome is extremely rare, but may occur, even in apparently uncomplicated cases.

Another group of cases warrants emphasis at this point, since it may provide one of the keys to the solution

of the problems of common respiratory disease. The group has been termed "bronchitis resembling atypical pneumonia" or "suspected atypical pneumonia,"¹¹ and includes cases differing in no wise from the description given above, save in the absence of a pulmonary lesion demonstrable by roentgenogram and in the somewhat lesser severity of illness. The characteristic subcrepitant rales, occurring unilaterally in most instances, give evidence of pulmonary involvement. On the basis of the best clinical evaluation which could be made,^{4, 5, 11, 22, 23} this group of cases seems to lie midway between primary atypical pneumonia and undifferentiated acute respiratory disease, without sharp border lines between the three groups (Figure 5). Epidemiological evidence appears to support this

DAY BEFORE ADMISSION
TO HOSPITAL

10th DAY IN HOSPITAL

FIGURE 4—Unrecognized infection, probably atypical pneumonia, discovered by routine roentgenographic examination. There were no symptoms except a cough of 3 weeks' duration. No pulmonary signs were evident until the fifth day in the hospital. Recovery was uneventful.

(Published in *War Med.*, 3:223, 1943.)

sulfonamide drugs is of no benefit in uncomplicated cases and should be instituted only if secondary bacterial infection exists or, rarely, as an aid to diagnosis. A long period of convalescence is required in many cases because of the persistence of localized symptoms or signs, and of asthenia. There is no specific therapy available. The use of convalescent serum has been reported,^{26, 27} but the evidence at present is insufficient to evaluate its effectiveness. Should primary atypical pneumonia prove to be a virus disease and thus be analogous to other virus infections, such therapy might not be expected to be of value from either practical or theoretical considerations.

EPIDEMIOLOGICAL ASPECTS

Primary atypical pneumonia is apparently a disease of widespread prevalence, both in endemic and epidemic form.^{8, 10-12, 28} No race, color, or sex differences in incidence have been observed. The disease may affect any age group, but the majority of the outbreaks have been described in adolescents and young adults. In the armed forces²⁹⁻³⁶ the syndrome has thus far been found wherever it has been sought, regardless of geographic boundaries. The incidence has varied, but in general has reflected the total incidence of respiratory disease.³⁷

The source of infection is probably the oral and nasal discharges of per-

FIGURE 5—Frequency of certain symptoms in atypical pneumonia and other respiratory infections.

(Published in *War Med.*, 3:223, 1943.)

sons with clinically recognized infections, of individuals with unrecognized infections, and possibly of healthy carriers. The mode of transmission is presumably by direct contact, or possibly by contact with articles freshly soiled with discharges from the respiratory tract, and by air-borne transmission. In the army camps thus far studied, there has been no evidence suggesting an intermediary vector such as food, water, or insects.

The incubation period is believed to be as long as 2 or 3 weeks, based primarily on the meager data available from a few instances of apparent case-to-case exposure. The period of communicability is entirely unknown.

Little is known about susceptibility and immunity to atypical pneumonia. It would appear that the population is not unusually susceptible in so far as clinically recognizable infections are concerned. Even during periods of relatively high incidence at an army

post, for example, cases appear scattered throughout the personnel as if they were distributed at random, and case-to-case spread is usually impossible to determine. The picture is thus very similar to that obtaining with meningococcal meningitis. Individuals who may be exposed closely and repeatedly to patients, however, may show a higher incidence of infection. This has been noted in the professional staffs of hospitals, both under civilian^{3, 26, 38} and military conditions.¹¹ Thus it might appear that susceptibility is low and that relatively high dosage, through close and repeated exposure, is necessary to produce the infection. It is, however, difficult to explain the spread of the disease on this basis. If "non-pneumonic" or "unrecognized forms" of the infection do exist as "suspected atypical pneumonia" and as undifferentiated respiratory disease, then susceptibility could be considered to be high and the distribution of the

"pneumonic form" could be explained.

The duration and nature of immunity are unknown. In all probability, any acquired active immunity is of short duration. During the past year at Fort Bragg, several instances of second attacks within a period of a year have been noted.

No specific measures for control are known at the present time, and only those general measures which can be instituted for any respiratory disease are available.

DIFFERENTIAL DIAGNOSIS AND ETIOLOGY

It is perhaps apparent from the above discussion that the final diagnosis of primary atypical pneumonia at the present time is an exclusion diagnosis, which can reliably be established only after other agents known to produce the same syndrome have been excluded, in so far as possible, in each individual case. Until a specific etiological diagnosis of primary atypical pneumonia can be made, certain representatives of each of the large groups of pathogenic microorganisms must be considered, including bacteria, fungi, rickettsiae, and viruses.

Bacterial pneumonias ordinarily are not difficult to differentiate from primary atypical pneumonia. The chief clinical features are abrupt onset, rigor, grossly bloody sputum, pleurisy, signs of pulmonary consolidation, and leukocytosis. Isolation of the infecting bacterium from the blood and sputum is usually readily accomplished, and such organisms as the pneumococcus, streptococcus, tubercle bacillus, staphylococcus, *Brucella abortus*, and *Pasteurella tularensis* may be obtained. In certain instances—approximately 10 per cent of hospitalized cases of primary atypical pneumonia—however, the differentiation may not be easy.¹¹ The onset may be sudden with rigor; the physical signs may be those of consolidation; a moderate leukocytosis may be present;

or pneumococci, particularly of the "higher" types, or hemolytic streptococci may be isolated from the sputum. In these cases a therapeutic trial of the sulfonamides often is of aid in establishing the diagnosis (Figure 6).

Of the fungus infections, only coccidioidomycosis³⁹⁻⁴¹ is of appreciable significance in the differential diagnosis. Mild acute cases without demonstrable pulmonary involvement may simulate undifferentiated respiratory disease, and cases with pulmonary lesions may closely resemble primary atypical pneumonia. Chronic infections with granulomata and localized lesions are more readily distinguished. The localization of this infection geographically in southwestern United States, the use of coccidioidin as a skin test, demonstration of the development of antibodies in convalescent phase sera, and isolation of *Coccidioides immitis* all serve to identify this disease.

The possibility that rickettsial infection, other than the well known typhus and spotted fevers, might be confused with primary atypical pneumonia became apparent in 1939.^{42, 43} Two years prior to this time, an apparently new disease entity, known as Australian-Q fever, was reported from Queensland, Australia.⁴⁴ The following year a similar organism was found in ticks in Montana.⁴⁵ In 1939, the same rickettsia was isolated from a number of cases which occurred at the National Institute of Health and which presented the syndrome of primary atypical pneumonia. The evidence indicated that this organism, *Rickettsia burneti*, was the causative agent. Apart from this outbreak, however, there is thus far no evidence that the agent is responsible for more than a few sporadic human infections.

The fourth group of agents, the known viruses, presents a more complex situation. Presumably the viruses of influenza A and B may alone produce

FIGURE 6—Atypical pneumonia having some of the clinical characteristics of pneumococcal pneumonia

pulmonary involvement, although the evidence in this regard is as yet scant.^{46, 47} Certainly the clinical and epidemiological features of influenza during an epidemic are quite distinct from those of primary atypical pneumonia, yet in an individual case the differentiation may be difficult, if not impossible. It is therefore necessary to employ laboratory aids in diagnosis, the simplest of which is to determine the development of specific influenzal antibodies by comparing acute and convalescent phase sera.

Psittacosis, which has long been known to be a virus disease, has more recently come to be considered as a group of diseases caused by the "psittacosis" or "ornithosis" group of viruses. Viruses of this type have now been isolated from a number of different

species of birds and animals,^{47, 48} including man.^{49, 50} Where a causal relationship has been established in patients, the clinical illness has in general been more severe although similar to that of primary atypical pneumonia. Attempts to relate this group of agents causally to primary atypical pneumonia occurring at Camp Claiborne, Fort Bragg, and other army posts, however, have been unsuccessful, in spite of the isolation of several strains of virus.¹¹ Confirmatory serological evidence could not be obtained from the patients' sera; in other words, an increase in antibodies was not demonstrable in the convalescent phase sera, and the level of antibodies appeared to correlate more with race and probable venereal exposure than with the respiratory disease under investigation. The close anti-

genic relationship of the virus of lymphogranuloma inguinale to the psittacosis group of viruses seems to provide the most logical explanation.⁵¹⁻⁵³ In addition, the possible saprophytic existence of the virus in man must be considered.

One other virus should be mentioned, namely, that of lymphocytic choriomeningitis. While the relation of this agent to respiratory illness has not been satisfactorily established, there seems little doubt that it can produce an influenza-like or grippe-like disease,⁵⁴ and in certain instances can cause pulmonary infiltration.⁵⁵

It should be emphasized again that the above mentioned agents, which can be recognized, are actually responsible in the Army for an almost insignificant number of cases showing the syndrome of primary atypical pneumonia. In the great majority of the cases no evidence has been obtained that any of the known bacteria, fungi, rickettsiae, or viruses play an etiological rôle.

The search for new agents has not been neglected. A number of groups of investigators have reported the isolation of viruses from throat washings, sputum, or blood of patients with primary atypical pneumonia. These agents have been obtained by inoculation of ferrets and mice,⁵⁶ mongooses,⁵⁷ chick embryos,⁵⁷ cats,^{58, 59} cotton rats,^{60, 61} guinea pigs,⁶² and mice after preliminary growth in tissue culture.⁶³ In no instance, however, has there been established a clear-cut relation between any one of the agents and the human disease.

The possibility that a laboratory test may be of value in the recognition of primary atypical pneumonia is suggested by recent reports⁶⁴⁻⁶⁶ of the presence of cold agglutinins for Group O human erythrocytes in the sera of some patients. The specificity and sensitivity of this reaction has not yet been determined in a sufficient number of cases

of primary atypical pneumonia and other respiratory infections to permit satisfactory evaluations. The data thus far obtained in the Commission laboratory at Fort Bragg indicate that the reaction may be positive in 25 to 50 per cent of cases of primary atypical pneumonia, and up to 10 per cent of cases of other types of respiratory disease, depending on the technic employed.

In summary, an attempt has been made to review the present status of knowledge concerning primary atypical pneumonia from the clinical, epidemiological, and etiological aspects. The importance of this problem to the military forces can only be estimated. In spite of the recognized difficulties in accurate diagnosis and reporting, the total number of cases recorded in troops in the continental limits of the United States from March, 1942, to May 8, 1943, was approximately 26,000.⁶⁷ The disease is not a significant factor in mortality, but is "an important cause of temporary disability, resulting in loss of man power hours and loss of days from training and other duties."⁶⁷ Primary atypical pneumonia is, numerically at least, the most important form of pneumonia affecting the armed forces today, and should it subsequently prove to be but a severe form of a more common undifferentiated respiratory disease, it will be one of the most important problems in therapeutic and preventive medicine facing the medical military services.

NOTE—This work was supported through the Commission on Acute Respiratory Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, United States Army, and by grants from the Commonwealth Fund, the W. K. Kellogg Foundation, the John and Mary R. Markle Foundation, and the International Health Division of the Rockefeller Foundation to the Board for the Investigation and Control of Influenza and Other Epidemic Diseases for the Commission on Acute Respiratory Diseases.

Antibiotic Substances, Production by Microorganisms—Nature and Mode of Action*

SELMAN A. WAKSMAN, PH.D.

Microbiologist, New Jersey Agricultural Experiment Station, Rutgers University, New Brunswick, N. J.

THE mounting interest in the production, utilization, and chemical nature of penicillin has recently focused considerable attention upon the whole subject of antibiotic substances and their formation by microorganisms. Although the nature and activities of some of these substances have been known for many years, the wide horizons that have now been opened for their practical utilization in combating human and animal diseases have attracted the attention of the bacteriologist, the chemist, the public health worker, and the clinician, not to mention the manufacturer who has envisioned a repetition, on a vastly wider scale, of the possibilities opened by the discovery of the sulfa drugs.

Formation and nature of antibiotic substances—Antibiotic substances are antimicrobial agents, produced by a variety of microorganisms found among the filamentous fungi or molds, yeasts, actinomycetes, and bacteria. They are chemically and biologically distinct from the common antiseptic and germicidal agents, although certain synthetic preparations may have properties similar to those of antibiotic agents. They

are primarily bacteriostatic in nature, that is, they inhibit the growth of bacteria, whereas their bactericidal activities are of only secondary consideration and require a longer period of time than that needed for ordinary disinfectants.

One of the characteristic properties of antibiotic agents is their selective antibacterial action. Some affect largely Gram-positive bacteria and act only to a very limited extent upon Gram-negative organisms; others, however, have the capacity of inhibiting the growth of certain bacteria belonging to each of these groups, and act only to a limited extent against other organisms within the same group. The selective action of antibiotic substances is not only qualitative but also quantitative in nature, much larger concentrations being required to inhibit the growth of some bacteria than of others. The term "antibiotic spectrum" is, therefore, justifiably used to designate a range of activity of an antibiotic substance against a number of bacteria selected from various representative Gram-positive and Gram-negative groups.

Antibiotic substances vary greatly in their chemical nature, in their mode of action upon bacteria, in their toxicity to animals, and in their *in vivo* vs. *in vitro* activity. Some are destroyed by boiling, by exposure to light, and by

* Journal Series Paper, New Jersey Agricultural Experiment Station, Rutgers University, Department of Soil Microbiology. Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

passage through various filters, whereas others are resistant to heat and to ultra-violet rays. Some are readily adsorbed by various adsorbing agents, such as active charcoal and infusorial earth; they usually can be removed from these by means of special solvents, such as ether, alcohol, chloroform, acetone, acids, or alkalis.

In order to obtain an antibiotic substance, an antagonistic organism is selected for its specific antibacterial activity and grown on an organic or a synthetic medium. The period of incubation usually varies from 3 to 20 days, and the temperature from 20° to 30° C. Since these organisms are aerobic in nature, proper aeration of the culture is essential; hence, shallow layers of liquid culture media for stationary cultures or forced aeration for submerged cultures are used. The formation of the antibiotic substance is greatly influenced by the strain of the organism, the composition of the medium, and the conditions of growth. Some antagonistic microorganisms produce more than one antibiotic substance. It has also been definitely established that some substances or closely related compounds may be produced by more than one organism.

Saprophytic and pathogenic microorganisms—There is no plant or animal now living that is not subject to infection by a number of bacteria, fungi, and protozoa, resulting in numerous diseases and epidemics. These disease producing microorganisms sooner or later find their way into the soil and into water basins, either in the excreta or in the dead and infected residues of the host. Fortunately, these natural substrates are not recognized at the present time as carriers of most of the common infectious diseases of man and animals. As a result of extensive investigations, the conclusion has been reached that most of the disease producing agents do not survive long in

the soil, but die out there at a rather rapid rate, depending on the nature of the organism, the nature of the soil, climatic and other conditions.

The antagonistic effects of saprophytic soil microorganisms upon pathogenic bacteria and fungi were at first visualized as resulting from competition for food between these two groups. It was soon recognized, however, that this was not a sufficient explanation for all the observed phenomena, included by Ward¹⁵ under the general term "antibiosis." Organisms living in associations were found to develop frequently certain characteristics that they did not possess when grown in pure culture. Schiller,¹⁰ for example, observed that when beer yeasts were placed together with tubercle bacteria in a sugar-containing but nitrogen-free medium, the former developed antagonistic properties toward the latter and used the latter as a source of nitrogen. The antagonists secreted a bacteriolytic substance that was also active outside the living cells.

Dubos⁴ used the method of enriching a soil with cultures of living pathogenic organisms in order to stimulate the development of antagonists that brought about the destruction of the pathogens. In order to isolate an antagonist from an ordinary soil or from one thus enriched, it is sufficient to inoculate a suspension of living bacteria with the soil, or plate out the soil on an agar medium with these living bacteria as the major nutrient, as suggested by Waksman and Woodruff.^{13, 14} A number of different antagonistic organisms have thus been isolated.¹²

The most important organisms known at the present time capable of producing antibiotic substances can be classified into four broad groups: 1. non-spore-forming bacteria, comprising *Pseudomonas aeruginosa* and various others; 2. spore-forming bacteria including *Bacillus brevis*, *Bacillus mesentericus*

and *Bacillus mycoides*; 3. filamentous fungi, especially members of the genera *Penicillium* and *Aspergillus*; and 4. actinomycetes, especially the aerial mycelium producing types of the genus *Streptomyces*.

The antagonistic action of *Pseudomonas aeruginosa* was first established in 1888 by Freudenreich,⁸ who believed that the lack of growth of various bacteria in the sterile filtrate of the antagonist was due to the exhaustion of nutrients in the medium. The filtrate possessed bacteriolytic properties, believed to be due to an enzyme designated as "pyocyanase" and to the pigment pyocyanin. Since pyocyanase is thermostable, not sensitive to pH change and not precipitated by ammonium sulfate and alcohol, but is soluble in alcohol, a lipid-like nature has later been suggested. This organism is now recognized as producing three antibiotic substances, including also hemipyocyanin. These substances differ in chemical nature and in their mode of action upon bacteria.

The production of antibiotic substances by spore-forming bacteria has long been established. This culminated in the isolation by Dubos⁵ of the antibiotic agent tyrothricin, which consists of two distinct substances, gramicidin and tyrocidine; these differ in their chemical nature, mode of action upon bacteria, and toxicity to animals.

Among the fungi, various green molds belonging to the genera *Penicillium*, *Aspergillus*, and *Trichoderma* have long attracted attention as organisms possessing antibacterial properties. Vaudremer,¹¹ for example, demonstrated in 1913 that *Mycobacterium tuberculosis* loses its virulence in the presence of *A. fumigatus* or its products.

The ability of a member of the *Penicillium* group to produce an antibacterial substance was first established by Fleming⁶ in 1929. This substance was designated as "penicillin." Vari-

ous strains of *P. notatum* and *P. chrysogenum* are now known to produce this antibiotic agent. Clutterbuck, Lovell, and Raistrick³ reported, in 1932, that these fungi produce three compounds, penicillin, a protein, and a pigment, only the first of which showed antibacterial properties. It was active largely against Gram-positive and certain Gram-negative bacteria, but not against most other Gram-negative bacteria. It was non-toxic to animals and was active *in vivo*.

This work attracted very little attention for nearly a decade until a group of Oxford chemists and pathologists^{1,2,7} decided in 1940 to reexamine the potentialities of penicillin for the treatment of various diseases. These investigations resulted in a series of contributions concerning the isolation, antibacterial properties, chemical nature, and mode of action of this important antibiotic substance.

It has been recently established that *P. notatum* produces, in addition to penicillin, another antibacterial factor, active not only against Gram-positive but also against Gram-negative bacteria. This substance was designated variously as the *Escherichia coli* factor, penatin, notatin, and penicillin B. It is a protein and functions as a glucose-oxidase. It has also been demonstrated that other fungi, notably members of the *A. flavus* group, produce a substance designated as flavicin that is similar to if not identical with penicillin.

Actinomycetes yielded several antibiotic substances; the most promising of these is streptothricin¹⁴ which is active against many Gram-negative as well as Gram-positive bacteria, has a low toxicity to animals, and is active *in vivo*.

A fairly large number of other antibiotic substances have now been isolated, but many of these are toxic to animals, possess undesirable physical, chemical, or biological properties, or

TABLE 1

Summary of Chemical and Biological Properties of Some of the More Important Antibiotic Substances

<i>Substance</i>	<i>Organism</i>	<i>Active Against Bacteria</i>	<i>Properties</i>
Actinomycin A	<i>A. antibioticus</i>	Selective quantitative action.	Soluble in ether and alcohol, not in petrol ether; orange colored; highly toxic; thermostable; nitrogen bearing ring compound.
Aspergilllic acid	<i>A. flavus</i>	Active against both Gram-positive and Gram-negative bacteria.	Soluble in alcohol, ether, acetone, not in petroleum ether. Acid nature. m.p. about 96° C.; m.w. 224; about 13 per cent nitrogen.
Citrinin	<i>P. citrinum</i>	Non-selective.	Soluble in water and in alcohol, precipitated by acid; quinone.
Clavacin	<i>A. clavatus</i>	Active against Gram-negative and some Gram-positive bacteria. Highly bactericidal.	Soluble in ether, chloroform, alcohol and water. Toxic.
Flavicin	<i>A. flavus</i>	See penicillin.	Similar in all respects to penicillin.
Fumigacin	<i>A. fumigatus</i>	Largely active against Gram-positive bacteria.	White, needle-shaped crystals; m.p. 185°-187°; soluble in alcohol, limited solubility in water.
Gliotoxin	<i>Trichoderma, Gliocladium</i>	Non-selective; fungicidal and bactericidal.	Soluble in chloroform, benzol alcohol, sparingly in water; contains nitrogen and sulfur.
Gramicidin	<i>B. brevis</i>	Lytic to Gram-positive bacteria.	Soluble in ether and acetone; thermolabile; active <i>in vivo</i> ; polypeptide.
Notatin	<i>P. notatum</i> and <i>P. chrysogenum</i>	On Gram-positive and Gram-negative bacteria.	Insoluble in organic solvents, soluble in water; acts, in presence of glucose.
Penicillic acid	<i>P. puberulum</i>	Active against Gram-positive and also upon Gram-negative bacteria.	Colorless; soluble in water.
Penicillin	<i>P. notatum</i> and <i>P. chrysogenum</i>	Acts largely upon various Gram-positive aerobic and anaerobic bacteria.	Soluble in alcohol and water; thermolabile; active <i>in vivo</i> ; low toxicity.
Proactinomycin	<i>Pr. gardneri</i>	Acts primarily upon Gram-positive bacteria.	Soluble in ether, benzene and water. Toxic.
Pyocyanase	<i>Ps. aeruginosa</i>	Lytic action on many Gram-positive and Gram-negative bacteria.	Thermostable; lipoid; activity largely due to unsaturated fatty acids.
Pyocyanin	<i>Ps. aeruginosa</i>	Bactericidal action largely against Gram-positive bacteria.	Chloroform-soluble, blue pigment; thermostable.
Streptothricin	<i>A. lavendulae</i>	Active on various Gram-negative and some Gram-positive bacteria.	Soluble in water and in acid alcohol, not in ether; organic base; thermostable. Low toxicity; active <i>in vivo</i> .
Tyrocidine	<i>B. brevis</i>	Lytic to Gram-positive and Gram-negative bacteria.	Soluble in alcohol, not in ether; thermostable; polypeptide.

have not as yet been studied sufficiently.

Chemical nature and activity of antibiotic substances—The antibiotic substances do not comprise a single group of chemical compounds but vary greatly in composition. Since very few of them have so far been crystallized and their chemical nature established, any system of classification of these compounds on the basis of their chemical relationship can only be tentative (Table 1). The following seven groups may now be recognized:

1. Polypeptides and proteins, including tyrothricin, lysozyme, actinomycetin, and notatin

2. Sulfur-bearing compounds, comprising gliotoxin and several others

3. Pigments, which include pyocyanin, hemipyocyanin, prodigiosin, chlororaphin, toxoflavin, and actinomycin

4. Lipoids and lipid-like bodies. (These comprise a number of compounds produced by different types of microorganisms; only some of which, such as pyocyanase, have been investigated.)

5. Quinones and quinone-bearing compounds, including citrinin, penicillic acid, and fumigatin

6. Organic bases, comprising streptothricin and proactinomycin

7. Agents which are known to be produced by various microorganisms but which have not been isolated or studied in detail

The methods for measuring the activity of antibiotic substances are based upon their bacteriostatic nature, their selective action against various bacteria and other microorganisms, and the mechanism or mode of their action. Some of the antibiotic substances are also fungistatic, and even fungicidal in nature, like gliotoxin, actinomycin, clavacin, hemipyocyanin, the *Bacillus simplex* factor, and others.

On the basis of their toxicity to animals, the antibiotic substances can be divided into three groups: (1) Substances non-toxic to higher animals or possessing but little toxicity, when 0.5 gm. or more per kg. weight of animal is tolerated; here belong penicillin, citrinin, pyocyanase, streptothricin, actinomycetin, and fumigacin. (2) Substances that are fairly toxic to animals, including tyrothricin, notatin, and gliotoxin; although limited information precludes establishment of a toxic zone for these, a range of 0.1 to 0.5 gm. per kg. can be suggested tentatively. (3) Highly toxic compounds, such as actinomycin, clavacin and aspergillilic acid; these are usually more toxic than 0.1 gm. per kg.; for many, such as actinomycin, as little as 0.15 mg. per kg. weight is toxic.

Of the various antibiotic agents, penicillin is the only one that has so far found an extensive chemotherapeutic application.⁹ It is effective against hemolytic streptococcus and pneumococcus infections, as well as various staphylococcal infections; it is used in controlling local lesions of the eye caused by *Staphylococcus aureus*; however, it has no effect upon infections caused by *Mycobacterium tuberculosis*, *Trypanosoma equiperdum*, and influenza virus. It is effective against sul-

fonamide-resistant strains of pneumococci, although pneumococcus cultures can build up resistance against penicillin. In order to overcome the instability of penicillin and its rapid excretion, esters have been prepared which are said to be more stable and even offer promise of use by oral administration. Next to penicillin in chemotherapeutic value is tyrothricin which is being utilized for the control of mastitis in cattle and certain local infections. Pyocyanase was extensively used at one time for the treatment of various infections, but because of its instability, the variability of the organisms producing it, and insufficient knowledge concerning the conditions governing its formation, its use has been discontinued or been very greatly limited.

Mode of action of antibiotic substances—The mode of action of antibiotic substances upon bacteria consists largely in interfering with cell multiplication. This may be accompanied by a marked effect upon certain essential metabolic processes. On the basis of the limited information now available, the following mechanisms may be tentatively presented:

1. The antibiotic substance interferes with bacterial cell division, thus preventing further growth of the organism; the cell, unable to divide gradually dies. It has been shown by the use of the manometric method, that certain bactericidal agents in bacteriostatic concentrations may have no effect on the metabolic rates of bacteria; however, they inhibit cell multiplication.

2. The antibiotic substance interferes with the metabolic processes of the microbial cells, by substituting for one of the essential nutrients.

3. The antibiotic substance may interfere with the vitamin utilization of the organism; the staling effect of a medium, frequently spoken of in the case of protozoa as "biological conditioning" of the organism, may serve as an illustration; such effects have been overcome by the addition of a mixture of thiamin, riboflavin and nicotinamide.

4. The antibiotic agents bring about the

oxidation of a metabolic substance which must be reduced in the process of bacterial nutrition, or otherwise modifies the intermediary metabolism of the bacterial cell.

5. The agent combines with the substrate or with one of its constituents, which is thereby rendered inactive for bacterial utilization.

6. The agent competes for an enzyme required by the bacteria in order to carry out an essential metabolic process.

7. The agent interferes with various enzymatic systems, such as the respiratory mechanisms of the bacterial cells, especially the hydrogenase system; penicillin was shown capable of inhibiting the activity of urease.

8. The antibiotic substance may inhibit directly cellular oxidations, particularly those involving nitrogenous compounds, similar to the action of propamidine.

9. The antibiotic substance acts as an enzyme system and produces, in the medium, oxidation products, such as peroxides, injurious to the bacterial cell. The glucose oxidase produced by *P. notatum* catalyzes the following reaction:

10. The antibiotic substance favors certain lytic mechanisms in the cell, whereby the latter is destroyed; this mechanism may be either secondary or primary in nature.

11. The antibiotic substance affects the surface tension of the bacteria, acting as a detergent.

12. Bacteria subjected to the action of an antibiotic substance may develop mechanisms that render them resistant to the action of the substance.

13. Some bacteria may produce an enzyme, such as penicillinase, that brings about the destruction of the antibiotic substance.

SUMMARY

The utilization of antagonistic microorganisms, directly or through the production of antibiotic substances, offers three distinct potentialities to help man in overcoming his ills as well as those of his animals and of his crops:

1. Domestication of microorganisms for disease control.
2. Isolation of new chemotherapeutic agents for combating human and animal diseases.
3. Utilization of the activities of microorganisms for combating various plant diseases.

We are faced with a new field of research, which overlaps the fields of biology and chemistry and unites medicine with soil science. Many secrets of nature not sufficiently understood heretofore, will thereby be unraveled and new agents that may help man in combating diseases and epidemics discovered. This new field offers further great possibilities for the study of the nature and physiology of the bacterial cell, which may lead to a better understanding of the way of life of the smallest and, in many respects, the most interesting of the living systems.

UNRRA's Public Health Plans

James A. Crabtree, M.D., acting chief of the Health Division of the United Nations Relief and Rehabilitation Administration, Washington, announced on February 21 the plans that are being made to deal with public health and nutritional problems in the occupied countries. Although it will be difficult to predict exactly what the conditions will be, Dr. Crabtree said that it was possible to make some intelligent guesses on what the conditions under a variety of premises might be, including what might be found under a completely scorched-earth policy.

Dr. Crabtree believed that the number one problem would be starvation, with all its relationships to public health, and he believed that increased death rates from maternal and infant causes, from malaria, and typhus, and from tuberculosis would have to be dealt with.

Dr. Crabtree felt that it was safe to predict that the breakdown of sanitary safeguards, together with crowding, lack of shelter, lack of clothing, fuel, soap, and the great movements of population would certainly result in epidemics. He said that some progress

was being made on the assembling of personnel for these purposes. At present the UNRRA supply problem is more advanced than the plans for personnel, but UNRRA is fully aware that medical supplies would be worth little without medical service. However, a few teams of physicians, nurses, engineers, and other health specialists have been organized and the plan will be to send into each country as it is liberated a relatively small, well rounded team of experts in various specialties of public health to consult with and to assist national governments in building up and strengthening their own medical care services and facilities. In addition special teams will have to be organized to deal with certain special problems such as epidemics and diseases that have been introduced into the country for the first time. Dr. Crabtree said that, while some of the occupied countries would need only the help of such general and special teams of workers, others which had been "scorched" of professional personnel might need a substantial number of doctors and nurses to come in and actually to help take care of the sick.

Human Serum Albumin as a Stabilizing Agent for Schick Toxin*

GEOFFREY EDSALL, M.D., AND LOUISE WYMAN

*Antitoxin and Vaccine Laboratory, State Department of Public Health,
Boston, Mass.*

A LITTLE over a decade ago it was found that gelatin or peptone added to diluted diphtheria toxin would prevent rapid deterioration of the toxin. This made it possible to distribute diluted Schick toxin ready for use. One of the most widely adopted diluents in this country and elsewhere was 0.25 per cent Witte peptone, recommended by White, Bunney, and Malcolm in 1932.¹

Beginning about 1934 there appeared scattered reports of acute generalized urticarial reactions immediately following the Schick test. These reactions were often severe and distressing, but never fatal. All cases showing reactions, on whom adequate histories were reported, had previously been Schick tested or had received immunizing injections. At the Antitoxin and Vaccine Laboratory we have received reports of 15 such reactions in the past 10 years, two of which have been observed by one of us. Similar reactions, following the injection of diphtheria or tetanus toxoid, have been reported by various workers. The conclusion of several investigators has been that the cause of these reactions is, in many instances at least, the presence of Witte or Berna peptone employed as a diluent or as a constituent of the medium.

In order to avoid these occasional

reactions, we sought a satisfactory stabilizing agent of human origin which would itself be stable. About this time small quantities of human serum albumin were made available to us through the courtesy of Dr. E. J. Cohn of the Harvard Medical School. His material was prepared under contract with the Committee on Medical Research of the Office of Scientific Research and Development. Human serum had been recommended as a stabilizing agent several years earlier by Glenny and Stevens,² but we preferred to work with human albumin, since the albumin represented a highly purified preparation of what was known to be the most stable of the important serum proteins.

A number of batches of Schick toxin have accordingly been made, using human albumin as a stabilizing agent. All of these preparations were made with Glenny, Pope, and Waddington's borate buffer³ as the fluid base. Potency has been tested (except where otherwise noted) by injection of 5 ml. subcutaneously into each of five guinea pigs of m.l.d. weight, observing the time of death of each animal. Stability of the toxin so prepared was, with but few exceptions, determined by heating samples for 24 hours at 37° C. (the official N.I.H. test) and at 41° C. (suggested by Glenny and Stevens). We have found the latter to be a very useful test of stability and one which gives an

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

TABLE 1

Efficiency of Albumin as a Stabilizing Agent Polency Tested by Subcutaneous Injection of 5 ml. into Guinea Pigs

Experiment	Stabilizer		Average Days Till Death of Guinea Pigs (see note 2)

‡ 6 guinea pigs

answer in a short time. For a preservative, merthiolate 1:10,000 was used except in certain experimental batches.

The principal findings have been as follows:

1. For adequate protection of diluted diphtheria toxin, 0.05 per cent albumin is apparently insufficient, whereas 0.1 per cent is adequate but is apparently not quite as good as 0.2 per cent.

2. The above does not apply where phenol is used as a preservative, since concentrations of albumin as high as 0.2 per cent have failed to prevent deterioration in phenolized Schick toxin incubated at 37° C. for 24 hours.

3. Several batches of Schick toxin stabilized with albumin have shown no significant deterioration after exposure

to 41° C. for 24 hours. This represents at least as high a stability as has been observed with any peptone-diluted toxin of our preparation.

4. No significant differences have been observed in Schick toxin prepared with three different lots of albumin or with two different lots of toxin.

5. Tests of albumin-diluted Schick toxins, according to the League of Nations standardization, have shown no significant differences from peptone-diluted toxin.

6. Duplicate Schick tests with albumin and peptone Schick toxin on 215 individuals, read at 4, 7, and, in some cases, 5 days, have shown certain minor differences. Opportunities for performing these tests were provided through

the kindness of Dr. Harold Norton and Dr. Roderick Dexter of the Massachusetts Department of Mental Health and Professor J. Howard Mueller of the Harvard Medical School. The albumin-diluted toxin as a rule:

a. Gave a brighter red positive reaction with more sharply defined borders.

b. Averaged somewhat smaller (209 sq. mm. as against 360 sq. mm. in comparable duplicate tests on 30 subjects).

c. In a few instances showed less tendency to fade by the 7th day.

d. Disagreed with the peptone reading in 13 of 70 presumably positive individuals. All of these disagreements represented a positive or combined albumin toxin reaction and a negative or pseudo peptone toxin reaction. Of the

8 of these 13 subjects on whom simultaneous serum antitoxin titers were performed, 6 were below 1/400 unit, indicating the validity of the albumin toxin readings.

Other studies on the material are being carried out and will be reported when completed. Meanwhile we recommend this preparation for further trial in the belief that it will prove suitable for general use.

Surveys of the Nutrition of Populations*

3. THE VITAMIN A NUTRITION OF A RURAL POPULATION IN MIDDLE TENNESSEE

JOHN B. YOUMANS, M.D., E. WHITE PATTON, M.D.,
W. R. SUTTON, PH.D., RUTH KERN, AND
RUTH STEINKAMP

*Department of Medicine and the Department of Biochemistry, Vanderbilt
University, Nashville, Tenn.*

IN previous papers the general nature of the study has been described and results with respect to the energy principle (calories) and protein have been reported. This communication describes the nutrition of the population with respect to vitamin A.

METHODS

Dietary—The general procedure for recording the intake of food has been described.¹ For calculating the amount of vitamin A the tables of Booher, Hartzler, and Hewston² were used. In each instance the value most closely and clearly applicable in respect to season, variety, preparation, etc., was chosen. In the few instances where values for foods were lacking in the above table they were taken from other sources and when no values for a food could be found one was assigned arbitrarily on the basis of similarity to other food or on similar grounds.¹ In no case did these arbitrarily assigned values affect the results significantly.

History and Physical Examination—The general procedure for obtaining the

medical history and for the physical examination has also been described.¹ For vitamin A, particular attention was paid to the history of such characteristic vitamin A deficiency diseases as xerosis, xerophthalmia, and the dermatosis; to night blindness; and to the symptoms of pre-xerosis, such as photophobia, burning and dryness of the eyes, asthenopia, and conjunctivitis. The taking of cod liver oil and other vitamin A preparations was also noted.

On the physical examination particular attention was directed to the skin and hair, to lesions of the eyes, and to vaginal discharge. A number of symptoms and signs such as the history and presence of respiratory infections, disorders of growth and development, abnormalities of the teeth and dentition and changes in the mucous membranes of the mouth and upper respiratory passages, whose significance to vitamin A deficiency is uncertain, were noted but are not analyzed here.

None of the symptoms and physical signs except those of the fully developed deficiency diseases are specific or pathognomonic for vitamin A deficiency, though some are of relatively high diagnostic value. It was necessary therefore to review these symptoms and signs in the light of the other evi-

*The studies referred to herein were conducted under the auspices of the International Health Division of the Rockefeller Foundation of New York City by the Nutrition Unit of the Departments of Medicine and Biochemistry of the Vanderbilt University School of Medicine, Nashville, Tenn.

dence obtained from the history and physical examination, and determine whether such signs and symptoms represented a vitamin A deficiency or were due to some other cause. This is clearly a matter of clinical judgment and must be based on experience with the manifestations of vitamin A deficiency states, the range of normal variations, and other causes of similar signs and symptoms. The decisions were made after a careful examination of each individual record without knowledge of the results of the dietary or laboratory studies, the original observations having been made by experienced examiners with an eye to such decisions. It is obvious, of course, that the probable correctness of the decision in each case must vary with the degree of specificity of the symptom or sign.

Laboratory Tests — The laboratory tests and special procedures included a test of visual adaptation to dim light (night blindness) and a determination of the amount of vitamin A and carotene in the blood serum.

The tests of dark adaptation were made with a Hecht and Schlaer adaptometer,³ measuring the rod threshold after a period of 20 minutes in complete darkness. Subjects, singly or in groups of 3 to 5, were seated in a completely dark room for 20 minutes after having been exposed to ordinary indoor light. After the 20 minute period of adaptation to the dark the light perception was tested according to the technic of the instrument. The purpose and nature of the test were explained carefully to each subject beforehand and every effort was made to secure satisfactory coöperation. At least three readings were made and the minimum value was taken. When there was any reason to believe the test was unsatisfactory it was discarded. Children under 4 were usually not tested and many above that age were unsatisfactory. An extensive experience with the instrument in

studying such things as the learning factor and the influence of age, and the use of the complete test (bleaching and regeneration) in the examination of many patients with a wide variety of diseases and complaints, contributed to a successful application of the test. Most of the tests were made by the examining physicians and all were made at the hospital where a suitable dark room and electric current were available. The machine bears the manufacturers' number 18 and does not have gelatin cemented lenses. The lamp was carefully standardized with the help of a physicist and checked at suitable intervals.

The upper normal value commonly used is 3.5 ± 0.3 micromicro lamberts. Because, however, of some unavoidable variability in the subjects' response in such a test and because of what appears to us to be a slight but definite increase in threshold with age we have taken 4.0 micromicro lamberts as the upper limit of normal. It should be remembered that the error of the instrument itself is probably less than the unavoidable error of the subject's response.

The concentration of carotene and vitamin A in the blood serum was determined by May's method.⁴ We found this micro-method may give slightly lower values than the macro-methods, but with a carefully controlled technic reliable values can be obtained. The lower limit of normal has been taken to be 70 International Units per 100 ml. of serum except in infants under 1 year of age for whom the value is 45 units.⁵

Blood was obtained from the sample drawn at the time of the physical examination, in most instances at least 3, usually 4–6 hours, after the last meal. About 30 ml. of venous blood was drawn with the least possible stasis in dry luer syringes. About 2 ml. was placed in a separate vial with an anticoagulant for hemoglobin determinations, etc. The remainder was placed

in a 50 ml. pyrex centrifuge tube and allowed to clot. Blood drawn at the hospital was sent immediately to the laboratory, centrifuged, and the serum removed. When drawn in the field it was placed at once in iced containers where it kept during transport to the laboratory. With few exceptions the blood reached the laboratory within 4 hours.

RESULTS

Vitamin A Intake—Table 1 gives the average daily intake of vitamin A (carotene and vitamin A, expressed as vitamin A) with the number and per cent of those in each age, sex, and racial group with intakes falling below the recommended daily allowances of the Food and Nutrition Board.*

According to these standards the dietary intake was deficient (insufficient) in a large number, ranging from 34 per cent in the 1-3 age group to 68 per cent in the girls 13-15, among the white subjects, and from 35 per cent in children 4-6, to 71 per cent in boys and girls 13-15, in the colored. Although there is some difference in the frequency between white and colored subjects in some of the age and sex groups, this is probably not significant except in the children 1-3 and the boys 13-15 and 16-20. In the children 1-3, the greater frequency of the deficiency in the colored may reflect the lower intake of milk. The difference in the other two groups is unexplained.

History and Physical Examination—No subjects gave a history of any of the characteristic diseases of vitamin A deficiency such as xerosis, xerophthalmia, keratomalacia, or the dermatosis. Two hundred and four complained of one or more of such symptoms of pre-xerosis as dryness, burning, and sand in the eyes, photophobia, asthenopia, and

conjunctivitis. Night blindness, generally considered a more specific symptom, was claimed by 60.

Symptoms of pre-xerosis were slightly more frequent in the colored than in the white subjects but much more striking differences were observed in some of the age and sex groups. In general the symptoms were much more frequent in adults (21 yrs.+), increasing from about 10 per cent in children, to 17 and 28 per cent in white, and 14 and 18 per cent in colored, men and women, but with a higher incidence in girls 13-15 and 16-20 which in colored girls amounted to 50 and 42 per cent. Night blindness occurred with equal frequency in white and colored, almost exclusively in adults and most often in white women.

Physical examination revealed no instances of well developed signs of vitamin A deficiency except for the dermatosis (eruption of the skin). Thirty-five subjects were found to have the characteristic dermatosis. Both the dry, horny, "goose flesh" type and the acneform type were observed. There were 12 instances of corneal scars which might possibly have been the result of lesions due to vitamin A deficiency in the past, and in 57 subjects changes were found in the sclera and conjunctiva which might be attributed to vitamin A deficiency. They consisted of the usual signs of conjunctivitis, redness and injection, sometimes dryness of the conjunctiva and such changes as a "muddy" and discolored (pigmented) sclera often with pingueculae or pterygia. Such changes are not very specific. The examination was made without reference to the findings, especially those detected with a slit lamp, described by Dr. Kruse, who had not yet published his observations.

The lesions in the eye, like the symptoms of pre-xerosis, and even night blindness, were by far the most frequent in adults. They were also found

about twice as often in men as in women and about twice as often in colored males (16 per cent) as in white males (8 per cent).

The dermatosis was found with equal frequency in the white and colored subjects but was practically limited to those past puberty. It was most common in the age group 16-20 and was found in one-fifth of the 40 white males of that age.

No significant association was found in the occurrence of the various symptoms and physical signs except that night blindness and the symptoms of pre-xerosis occurred together more frequently than either occurred in the total population. For example, night blindness was found in 16.7 per cent with symptoms of pre-xerosis but in only 5.5 per cent of the entire population. A vitamin A intake below the recom-

mended allowance was no more frequent in those with symptoms and physical signs of a deficiency than in those without.

Adaptometer—The results of the adaptometer tests are shown in Table 2 together with the percentage of those

in the various age, sex, and racial groups showing an abnormal response. Among the entire group, nearly half (47 per cent) had an abnormal adaptation of vision to dark as measured by this test. The abnormality occurred most frequently in the adults, both white and

* Twenty-five children under 1 year of age have been omitted.

† M = Male; F = Female.

colored, and was slightly greater in the negroes and in the women. Among the children the groups with the highest incidence of poor adaptation were the white and colored boys 13-15 and the colored children 4-6. However, only 4 of the latter of these were tested and the number of white children 4-6 years who were tested was also very small. No positive relationship statistically significant was found between heightened threshold (poor adaptation) and night blindness, the symptoms of xerosis, or the dermatosis. Curiously there appears to be a significant correlation between the occurrence of an elevated threshold and changes in the sclera. In subjects with the latter an elevated threshold was found in only 28 per cent compared with 49 per cent in those without these changes. The percentage difference was 21 ± 6.8 .

Blood Vitamin A—The values for vitamin A concentration in the blood serum are given in Table 3† together with the percentage of the subjects in the various age, sex, and racial groups with values below the lower limit of normal. Because the determination of vitamin A in the blood was not introduced until near the end of the first examination period, determinations were made in only 450 of the subjects, but the number in most of the groups is large enough to be significant. Among the white subjects the highest incidence of an abnormally low concentration is found in the younger children (1-12), though many of the girls 13-15 and 16-20 had low values in sharp contrast to boys of the same age. Boys 13-15, and men 21+ least often had a low vitamin A concentration. A striking finding is that greater frequency of low vitamin A values seem to be more frequent in the whites than in the negroes,

the difference being considerable in all groups except the youngest children (1-3).

There appears to be no relation between low blood vitamin A concentration and the occurrence of night blindness, the symptoms of xerosis and the dermatosis. However, an intake of vitamin A below the recommended allowance was somewhat more frequent (68 per cent) in those with low blood vitamin A than in those with normal blood values (46 per cent), a difference of 22 per cent ± 3.5 . An apparently significant inverse correlation is found between low blood vitamin A values, physical changes in the sclera and high adaptometer values. Only 7 per cent of the 42 subjects with changes in the sclera who have blood vitamin A determinations had low blood A values, compared with 30 per cent for those without such eye changes, a percentage difference of 23 ± 7 . Of the 95 with blood vitamin A below 70 I.U. only 17, or 18 per cent, had adaptometer readings above 4 micromicro lamberts, while 52 per cent of the group with normal blood vitamin A values had such adaptometer readings, a percentage difference of 34 ± 5 .

DISCUSSION

There are three aspects of these results which are of particular interest and importance. They are: (1) the relatively large amount of vitamin A deficiency as indicated by the dietary intake records, the adaptometer test and the vitamin A level in the blood, (2) the relative scarcity of symptoms and physical signs of a deficiency, and (3) the lack of correlation between all these various measures of vitamin A nutrition.

According to the dietary records there was a deficient vitamin A intake in 48 per cent of the population as a whole and in a much larger proportion of certain groups, and, by that measure, a presumable vitamin A deficiency *state*

* Figures following \pm sign refer to standard deviation of the difference.

† The values for carotene in the blood serum have been omitted to conserve space.

in a similar number. But, dietary intake as recorded here, and as a practicable procedure under similar circumstances, is not an accurate or reliable measure or test of the actual state of nutrition in respect to vitamin A. This is even more true of vitamin A than of some of the other nutritive factors because of the greater storage and reserve capacity in case of vitamin A. With this greater reserve the defects and errors inherent in a record of dietary intake over a necessarily limited period of time are exaggerated. The limitations of the dietary intake method are particularly great at the level of a slight deficiency, the indeterminate zone between no deficiency and some deficiency. Only in the more severe dietary failures, and in monotonous diets of limited variety and fixed quantity do intake records reach any considerable degree of reliability in the *assessment* of individual nutrition.

A second factor which must be taken into account in the interpretation of the results is the standards which are used. Those of the Recommended Allowances, while probably desirable to foster a liberal intake of an important nutrient, may be higher than are needed to protect against a true physiologic deficiency as recognizable today. Use of such standards increases the apparent deficiency indicated by the dietary intake.

The measurement of the rod threshold for light perception as a test of vitamin A deficiency is similarly open to criticism, not only of its accuracy but of its specificity. Measurable impairment of dark adaptation undoubtedly occurs in vitamin A deficiency but a variety of errors, mainly subjective, cause some unreliability, particularly at the level of slight impairment, and there are other causes of impaired dark adaptation than vitamin A deficiency. Some of these sources of error are particularly operative in the mass examination of popula-

tions and are of less importance in tests of individual patients. The opportunity to make repeated and more complete tests, to search for evidence of other disease, and to use the therapeutic test enhance greatly the reliability of the adaptometer test in clinical practice.

Just how reliable test is under the conditions of this survey is uncertain. In such a general population, error from such causes as retinitis pigmentosa, which is very rare, and anoxia in the usual sense must be very small, particularly because the complete history and physical examination helped greatly to exclude such causes. However, we have observed in other studies a distinct tendency to elevation of the rod threshold with advancing age. Examination of the data under consideration shows a direct relation between increasing age and the proportion of those with an elevated threshold, the latter rising very sharply to over 70 per cent in those beyond 40 years of age. Furthermore, thresholds of 5 micromicro lamberts or over were more than 12 times more frequent in persons over 40 than in the younger subjects. Experience under comparable conditions and with a similar group of people in whom the effect of administering vitamin A under adequately controlled conditions was studied suggests that in about 50 per cent of the cases the finding of an elevated threshold by this technic represents a vitamin A deficiency or an elevation which can be reduced by the administration of vitamin A (cod liver oil). Finally it should be pointed out that the instrument allows a very delicate measurement of light perception, that at the levels of the slightest or earliest deficiencies the subjective error of the subject's response may exceed the instrumental error, and hence slight variations from the accepted normal are of little significance, at least under the conditions of such a survey as this.

Fewer objections can be made to the concentration of vitamin A in the blood plasma or serum as an index of vitamin A nutrition. Conditions other than a deficiency of vitamin A may at times affect the level of vitamin A in the blood but in most population groups they are an insignificant factor. (In individual patients such cases are ordinarily revealed by the examination.) Temporary variations may be caused by fluctuations in recent intake and the use of blood analysis as a test of vitamin A deficiency has been objected to on these grounds. However, falsely high values, not representative of the general body store and state of nutrition, are unlikely in a deficiency unless there has been recent ingestion of exceptionally large amounts, a fact which can be ascertained from the history. On the other hand it has been quite clearly shown that individuals with normal stores when placed on a reduced intake do not suffer from a reduction in the concentration in the blood for long periods, until, indeed, an actual deficiency of at least the reserve store develops.⁶ Consequently, deprivation for short periods is unlikely to cause a false low value in individuals actually in normal nutrition, i.e., unless there actually exists a deficient reserve.

Assuming that the concentration of vitamin A in the blood reflects the general level of vitamin A and the reserve stores in the body and that under the conditions of such a survey as this it is not unduly influenced by extraneous factors and temporary fluctuations in vitamin A intake, the significance of an abnormally low concentration as an index of vitamin A deficiency may still be a matter of dispute. Actually it depends on the definition of vitamin A deficiency. If by vitamin A deficiency is meant the presence of demonstrable signs of disturbed function or structure, a low blood vitamin A is not a reliable sign of deficiency. Low con-

centration of vitamin A in the blood is found without evidence of disturbed function or structure, and the latter are observed without low vitamin A of the blood because the latter responds more quickly to increased intake of the vitamin. In view, however, of the inability to detect the earliest disturbances in function and structure, or to determine at what level of reduced blood or body content and store they first appear, the concentration of vitamin A in the blood may be used as an index of vitamin A nutrition and a concentration below the generally established "normal value" may be taken as evidence of a deficiency. Certainly the lack of an adequate and usual store or reserve, which under usual or "normal" circumstances protects against actual deficiency during periods of temporary shortage of supply or increased demand, can be taken, especially for public health purposes, as an abnormal state and a deficiency in a practical sense.

In contrast to the relatively frequent state of vitamin A deficiency disclosed by the diet record, the adaptometer readings and the blood vitamin A tests, the amount of deficiency revealed by history and physical examination was surprisingly meager. The greater number with *symptoms* is probably a reflection of the lesser reliability or specificity of these manifestations. Although many of the complaints of dryness of the eyes, burning, asthenopia, etc., may have been the result of mild vitamin A deficiency there is absolutely no means of distinguishing such cases with certainty from similar symptoms with other causes. Furthermore, a lack of correlation between the symptoms and physical signs and such evidences of deficiency as the dietary intake and laboratory tests cannot be taken as an indication of the reliability of those symptoms and signs for reasons to be discussed below. It may be observed however that these remarks apply only

when the signs and symptoms are an expression of mild deficiencies. Night blindness for example is probably a highly reliable symptom when it is severe.

Objective physical evidence of a deficiency was even less frequent than symptoms, as is to be expected, but, at least in respect to the dermatosis, is more reliable. Doubt of the value of the dermatosis as a sign of vitamin A deficiency has been expressed but without sufficient consideration of the factors involved in the diagnosis and interpretation of the lesions. Highly nonspecific changes such as "dryness," "roughness," and "redness" have been given undue weight. Though frequently found with the characteristic eruption they are only a few among several changes and of little value in themselves. As do other characteristic eruptions, the dermatosis of vitamin A deficiency has features of location, distribution, pattern, size, color, shape, and consistency of the individual lesions which distinguish it from other eruptions. The hyperkeratotic follicle is one of the individual lesions of the vitamin A deficiency dermatosis but a hyperkeratotic follicle, or several of them, is not *the* dermatosis. It is true that at best the dermatosis is not pathognomonic. It is however a sign of considerable reliability and meaning when properly identified. Unfortunately, under the condition of the examination used in this survey the results of the examination of the conjunctivae cannot be so definitely evaluated.

The third feature of particular interest in the results is the lack of correlation and agreement between the various indices or evidences of vitamin A deficiency. Such a lack of agreement might be thought to indicate such a lack of reliability of one or more of the procedures, tests or signs as to impair the value of the survey. Yet, con-

sideration will show, as already stated, that such agreement need not necessarily be found or expected. The intake of vitamin A may fail to accord with the concentration in the blood because there has not been time for the latter to reflect recent changes in intake, particularly when the fluctuations in intake are not greatly above or below the minimum requirements. Only in respect to the rod threshold (adaptometer) might close correspondence be expected with the intake of vitamin A (elevated thresholds may respond promptly to increased intake of vitamin A), but even then good correlation might be obscured by relatively slight changes in vitamin A intake and the effect of subjective error on the detection of slight changes in the threshold. Finally, there is the possibility, for which some evidence is accumulating, that other variables than those previously known or suspected are concerned, in addition to vitamin A, in visual adaptation to the dark (adaptometer).

Correspondence between the symptoms and the physical changes and the intake of vitamin A, the blood concentration of vitamin A, or the adaptometer value is even more unlikely. The symptoms (except night blindness) and physical changes are slow to develop and slow to disappear, requiring weeks or even months and hence often lagging far behind changes in the other indices.

It is necessary therefore, to take these various manifestations, the symptoms, the physical changes, and the laboratory tests as independent signs of a deficiency, differing in their reliability and specificity. Also they have a differing quantitative significance, reflecting variations in the severity and to some extent in the chronicity or duration of the deficiency.

SUMMARY

On the basis of this discussion the

nutrition of the population as respects vitamin A may be summarized as follows: There was a deficient dietary intake of the vitamin in a large proportion of the population according to the standards of sufficiency adopted. This deficiency of intake was not accompanied by a correspondingly high incidence of symptoms or physical signs of a deficiency, only a relatively small number of the subjects exhibiting this evidence of a deficiency. On the contrary, the test of dark adaptation and the concentration of vitamin A in the blood indicated a degree of deficiency somewhat comparable to that suggested by the dietary intake. Reasons are given why test of dark adaptation may not be a reliable measure of vitamin A deficiency, but the concentration of vitamin A in the blood is believed to be a significant index of vitamin A nutrition. It should be emphasized that the manifestations of a deficiency vary at different levels of intensity and duration and according to the definitions of the deficiency.

Neither the deficiency of intake nor the objective manifestations of a deficient nutrition were distributed equally among the various age and sex

and racial groups. While the explanation for some of these differences seems quite clear, others are at present unexplained.

Wartime Problems of a County Health Officer*

HUBERT O. SWARTOUT, M.D., DR.P.H.

County Health Officer, Los Angeles, Calif.

SOME of my wartime problems arise from within my department. Others press on it from without. First, of the inside problems, there is the heavy loss of personnel—to the armed forces, to high salaried jobs in war industry, to better paid employment in other governmental organizations, and, in the case of many of the former women employees of the department, to an easier life at home, where the income of the husband is now enough to make it no longer necessary for the wife to work. Second, for those who stay by the department, most of whom are older and less energetic to begin with than those who have left it, there is the discouraging effect of their low salaries in the face of high living costs, also the general feeling of uncertainty which nobody seems able to overcome, depressing their morale. Third, there is the insistence of some of my ambitious fellow workers that the department adopt new policies and move into new fields whenever anything opens the way.

First, of the outside problems, there are the new projects that certain popularity-hungry people think up and shout about, then look around for some "George," too frequently the health department, upon whom they can throw the burden of doing the work. Second, there are the official visitors who call to find out what we are doing and how we are doing it, and then suggest that we stop doing this or start doing that or change our ways to

conform to this or that model, etc. Third, there is the slowness with which tax-supplied funds grow, and the equal slowness with which some of those who control the funds seem to grasp the fact that now is the time when the health department ought to be able to meet new and increasing needs with augmented strength. Lastly—at least the last that I shall mention—there is the public, more upset and more fearful about almost everything now than ever before, and more often and more insistently than ever demanding that the health department "do something about it."

It is unnecessary to discuss in detail all of the problems I have mentioned. In some cases, little more than the brief statement already given is needed to make them clearly understood. In others, it seems best to explain further and to give some examples, duplicates of which, I feel sure, can be supplied from other jurisdictions.

When it comes to fellow workers leaving the department, what else can one do than give his best regards and good wishes to those who join the armed forces? And those who leave to take up high salaried jobs in war industry can hardly be blamed. As to those who go to better paid employment in other governmental organizations, I feel impelled to hold them up to the men who handle the county money bags as an argument for raising salaries. I can hardly expect them to compete with our state at present, because the California treasury has more loose money in it now than at any pre-

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

vious time in my recollection. But I look at Los Angeles City, our big neighbor, which has a hard time to find money enough to put concrete patches on an old sewer outfall down in the surf and keep it in operation for a while longer, to say nothing of being able to finance an adequate sewage treatment plant and free those ten miles of our beautiful beaches from quarantine; and I complain loudly: "Why should we pay our nurses less than the City Health Department pays?"

Now, what of those who stay by the department? While there does not seem to be much change possible in the general low salary level in local government, and there is little that can be done to relieve the feeling of uncertainty about what lies ahead, these conditions do present a challenge to me, and, I believe, to the head of any department of local government.

We must support morale by being as sympathetic and human in dealing with our fellow workers as it is possible to be. This is no time for a county health officer to put on the high hat or to tighten the thumb screws.

I can appreciate the attitude of my ambitious associates who see what they consider opportunities for the department to spread out into broader fields. They believe that if we do not occupy these opening fields, somebody else will; and then later we may find our own work disappointingly small and circumscribed. For instance, a year or so ago there was an increasing demand for part-time bedside nursing care in many of our communities. Some of our leading nurses felt strongly that we should begin a bedside nursing service, lest the newly-born Visiting Nurse Association undertake the work and earn the good will that they thought ought to be ours. I did not think we had force enough to attempt it then; and now, with a force of nurses so greatly depleted that we are not even able to

maintain the services which we have for many years considered essential, we certainly would find ourselves in a very embarrassing position if we had led the public to believe that we could take on the bedside nursing burden too. It is all right to grow, but not so good to swell.

I wish there were time for a more extended discussion of the merits and demerits of my department's entering further into the field of giving medical care to the people. With regard to what may be done to promote positive health through education about nutrition and desirable health habits, I do not hesitate to urge my department staff to go the limit. And I do not consider myself out of place in promoting general knowledge about common illnesses and simple home treatments for them. In these respects, many of our citizens are not as far ahead as their grandmothers were, and I think public health people are elected to help win back the ground lost on this front and to make still further advances. That, admittedly, is only the fringe of medical care.

I know that many believe the time will eventually come, and perhaps in the not-too-distant future, when the medical care of a considerable proportion of our citizens will be given, or at least organized and supervised, by health departments. I confess to being somewhat slow in moving very far in this direction. In my county, the medical care of the indigent is already set up under the Charities Department, and no department likes to diminish its importance by turning over any considerable part of its established activities to another department. Furthermore, we have the California Physicians' Service and the Group Hospital Plan in operation, and I think these organizations should be given a fair chance to show what they can do. Fundamentally, of course, it is up to the

people to say what kind of medical care they want, who shall give it, organize it, or supervise it, and how it shall be paid for. It is possible that some day organized medical care under government auspices will come into general being, and that by public demand health department doctors will have to take a leading part in it. If that day comes, I of course want to be ready for it.

It is, for this and other reasons, one of my most vital problems as a county health officer to keep in touch with the current of public opinion in my territory, so that I can not only know what is needed and wanted from day to day, but can foresee trends and tendencies to some extent. I should even, within reason, try to mold public opinion; but I should not walk too far in advance of my public. A drum major is an inspiring sight and serves a good purpose marching in front of his band; but he would look silly and be useless prancing up the street two or three blocks ahead.

When it comes to outside problems, I know of no way of heading off people who want to be looked at as saviors of their community in this "time of peril," but who also prefer to have somebody else do the work which their bright ideas make necessary. I shall never forget a remark made by the elderly watchman of the parking lot beside our office building, apropos of local activities, mostly talk, in the early months after Pearl Harbor. He said, "Well, Doc, the trouble with this here business is that there is just too many guys that want to be heroes." It is not always easy for a county health officer to save time enough to attend to his own business in the midst of such conditions without seeming to be uncooperative or even an unpatriotic obstructionist.

I am happy to say that our official visitors, who sometimes come in the flesh and sometimes in the form of

pamphlets with imposing titles, and who months or years ago were inclined to be critical of what we were doing and how we were doing it, have more and more come to see that communities differ, and that each one must settle its questions and do its work more or less in its own way if it is to be done to the best advantage.

One lasting memory, however, is the way that pressure was applied to my illustrious predecessor to recruit a large force of volunteer sanitary inspectors, the estimated needs running all the way from ten to forty for each of our twelve districts. Under this pressure, an earnest effort was made to find volunteers for such work. We finally succeeded in bringing a few small groups together here and there, but when we started to train them they began to evaporate. Within a few months there was hardly one left. Nobody is trying to tell me now that this plan will work in Los Angeles County.

During the early weeks of my own administration, I was plagued with the proposal that all of my regular inspectors be provided with emergency driving permits and blackout driving lights. They were also to be organized so that they could rush out into the field in case of a bombing raid to take care of food, water, and sewage problems caused by the explosions. Of course I wanted them ready when the raid was over and daylight came to take care of all emergencies that properly fell to them; but just what they would be able to do in the dark with food stocks and water and sewage systems, and with air raid wardens, policemen, firemen, utilities crews, emergency medical squads, etc., swarming around, I was never able to see. Still, I did not know for a while whether or not I could dodge this ill-timed activity without being looked at as next door to a traitor.

As to the county officials who have to estimate the distance to the bottom

of the tax barrel in deciding how much support will be given to the health department, I sympathize with them. They cannot, in many instances, do what they want to do. But they always have *some* leeway, and it is my problem to guess how much time and pressure I should employ in keeping them informed about the changing public health needs of the people, the effect of wartime conditions on our working staff, and how much, under the circumstances, I think they ought to do about these things. If I put on too little pressure, I fail to do my duty. If I put on too much, I succeed only in making myself a nuisance.

Now let us give attention to a perplexed and apprehensive citizenry. I have lost all hope of keeping up with their multiplied appeals, yet must daily take care that I do not become callous to them. The wife of a defense plant swing shifter wants me to keep neighbor A's roosters from crowing and neighbor B's pup from barking, so her husband can sleep. One dog lover wants me to sponsor an ordinance that will insure a type of inspection of animals slaughtered for pet food as good as that which is available in packing houses producing meat for human consumption; for, you see, wartime conditions have resulted in a poorer quality of dog food on the market.

One wants me to make the organization of sanitation districts my immediate purpose and chief aim in life. Every few days he comes in and repeats his arguments: Will not the lack of sewers breed filth? Will not filth breed epidemics? Will not epidemics ruin the country that the boys on Guadalcanal are dying to save? Another wants me to rid his chicken farm of rats. Are not rats a plague menace?

Dozens—one or more almost every day in the summer months—insist that I do something about the mosquito pest. It is hard to describe the feeling of

weariness and frustration that results from having to explain over and over during the mosquito season that, in California, state laws specify that mosquito control shall be carried on under the Mosquito Abatement District plan, and that the health department cannot legally spend money on it, especially when one knows that many of the complainants suspect the explanation is only a "brush off." To get around this point, one citizen insists that the mosquitoes in and around his home are the kind that can carry malaria, therefore I should exterminate them as a means of preventing the spread of communicable disease. When several of them are caught, and identified by the best authority in the West as not being anopheline at all, let alone being malaria vectors, he does not act as if he is yet convinced; and I have no doubt that he thinks, and perhaps tells his neighbors, that the health officer is neglecting his duty.

Then there is the poor lady, sensitive to oleander blossom pollen, who thinks the bulk of disease in many parts of the county is due to oleander poisoning. She asks me if it is not as important to head up a campaign to destroy all the oleander bushes in the county as it is to be concerned about the increasing prevalence of rabies.

But time makes me put a stop to this account, though there is no end to the story. I have to confess to being a poor drum major, with a band that I can seldom keep either in step, in time, or in tune. Still I resolve to trudge persistently along waving my health baton, with both ears and one eye on the band to keep it in plain sight and hearing, and the other eye on the road ahead. Without that forward look, both the band and I would probably fail to make the right turns when the time came, and eventually find ourselves lost in some pseudo health street with a dead end.

Procurement and Assignment— The Industrial Hygiene Problem*

CLARENCE D. SELBY, M.D., F.A.P.H.A.

Chairman, Committee on Industrial Health and Medicine, Procurement and Assignment Service, Detroit, Mich.

WHEN the United States entered the war there was a bank of some 300 trained industrial hygiene personnel, exclusive of physicians. Many of these have been absorbed by the military forces, the U. S. Public Health Service, the Maritime Commission, and other federal agencies, as well as by state and local bureaus of industrial hygiene. These agencies are not at present recruiting industrial hygiene personnel. However, should they need any, applicants will be cleared through the Procurement and Assignment Service for Sanitary Engineers of the War Manpower Commission.

This service is now operating under a definition of essentiality which is designed to assure state and local industrial hygiene agencies one industrial hygiene engineer for less than 500,000 of labor population, two for 500,000, and one more for each additional 500,000. This may or may not assure a sufficiency of service. Regardless of that, the pressing problem of the war industries, in so far as industrial hygiene is concerned, is not in the official agencies and in the services that they can render but in the industries themselves.

Prior to the war there were not too many in-the-plant industrial hygiene engineers. The expansion in personnel had occurred mostly in the state and local official agencies and this was stepped up greatly by the declaration of

war. When industry sought to employ them, trained and experienced persons were not available. A training program was attempted but it failed to progress much beyond that which was developed by the Division of Industrial Hygiene of the National Institute of Health, which did not increase the availables for industry.

So, except for the services supplied by the official agencies, the industrial hygiene activities of industry have been, with some few exceptions, and will be, definitely curtailed for the duration. The help of the official agencies is valuable and, of course, it is appreciated. But limited in personnel as they are by the definition of essentiality, their services to industry must necessarily also be limited—exceedingly so. These agencies cannot give day to day service, nor can they follow through. They can make surveys and they can counsel with industry; but the war industries need more than that to maintain control over exposures.

Concurrently with these developments have come further changes and additions in occupational disease laws, making them more stringent and inclusive. Industry has attempted to meet the situation after a fashion. Plant physicians, nurses, chemists, and safety men have picked up practical information with respect to certain exposures peculiar to their plants and with the aid of official agencies they have done quite well. The safety people have been especially interested and active

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

and they have done very well indeed, particularly in the prevention and control of air contamination.

In view of the foregoing, the Michigan Industrial Hygiene Association has deemed it wise to encourage and improve this lay assistance, and in doing so, special consideration is now being given to safety personnel. The most notable effort in this direction is now being projected at the request of the Industrial Hygiene Association by the School of Public Health of the University of Michigan. The first move is an "In-Service Training Course in Industrial Hygiene for Plant Safety Personnel" at Ann Arbor, during October, 1943. There appears to be a sufficiency of importance in the course to warrant a rather complete description.

It is planned to be a course of instruction, not a convention or a conference. A special faculty group is brought together for the occasion, composed of speakers who are recognized authorities. Each has been chosen for his familiarity with certain industrial problems, his contacts with plant safety personnel, and his capacity for practical application of technical information, as well as knowledge of the subject he will discuss. While the course will consist of a series of lectures by different speakers, it will provide continuity of instruction, with special bearing on environmental control procedures concerned with the prevention of occupational diseases and their implementation by safety people.

Although the course is for safety personnel, some physicians have registered and will be in attendance. However, there will be no discussion of industrial medical, nursing, and accident prevention procedures. If there seems to be a demand for this type of instruction, and there appears to be already, it will be handled in subsequent courses.

Supplementing the lectures there will be a group of informative educational

exhibits on: (1) Protective clothing; goggles, respirators, and other commonly used protective devices. (2) The instruments and equipment used by industrial hygiene engineers in making environmental surveys. (3) Simple, but effective, home-made goggle-cleansing, and boot and glove-cleansing stations used in certain plants.

The subjects to be discussed are:

- Significance of Industrial Hygiene
- Relationship of the Safety Engineer to Industrial Hygiene
- Environmental Aspects of Industrial Hygiene
- Control of Solvent Vapors and Acid Mists
- Control of Smokes, Fumes and Gases
- Evaluation and Control of Dust
- Safe Operation of Solvent Degreasers
- Foundry and Forging Practices, Moulding, Core Making, Shake-out, Cleaning, Heat Treating, etc.
- Metal Finishing, Machining, Grinding, Welding, Plating Metal Cleaning and Painting, etc.
- Plastics, Formaldehyde, Resins, Impregnation, Curing Fabrication, etc.
- Industrial Ventilation Practices
- Applications and Limitations of Respiratory Protective Equipment
- Personal Protective Clothing and Equipment
- Causative Agents of Industrial Dermatitis
- Dermatitis Preventive Measures
- Modelling of Women's Protective Clothing
- Legal Interpretation of the Recent Modifications of the Michigan Workmen's Compensation Act
- Plant Sanitation
- Maintenance and Its Relation to Safety and Health
- How to Make a Survey for Health Hazards
- How to Sell Industrial Hygiene to the Worker
- How to Utilize the Resources of Official and Private Industrial Hygiene Agencies

SUMMARY

The industrial hygiene problems of Procurement and Assignment are now limited largely to industrial plants. New well trained personnel are not available. Industry is temporizing with lay assistants and thinly spread help from the official agencies. Safety personnel have become interested and are doing very well. A special course for their instruction has been discussed.

DDT

ONE of the gravest health problems which will confront our Armies of Occupation in Europe (a problem already encountered in the Naples area) is the threat of typhus fever. The dislocation of populations, the lack of soap and of fuel for heating water, and the contributory influence of malnutrition will certainly confront us with the same situations which arose in the retreat of Napoleon's armies from Moscow and in the years of the Russian Revolution and the mass migrations which followed the First World War.

Fortunately we have at our disposal new control methods which are infinitely more powerful than those we possessed a quarter of a century ago, in the cumbersome procedures of heat disinfection (the Serbian barrel, for example) or the mass treatment of clothing by gaseous disinfectants.

Early in 1941, the Preventive Medicine Service of the Surgeon General's Office of our Army began an intensive study of insecticides and insect repellents; the exhaustive investigations made in the last two years have indicated the remarkable potency of dichloro-diphenyl-trichloroethane (DDT). This substance, synthesized by a German chemist in 1874, was suggested by a Swiss chemical firm in 1939 as an insecticide to be used against moths and plant lice. In May, 1943, DDT was adopted by the Army as the standard louse powder. One application of this powder is effective for 3 to 4 weeks, unless the powder is removed by washing. It can be applied by hand and power dusters without removal of the clothing. It is also possible to impregnate underwear with DDT; and in preliminary tests such underwear has retained its effective power for 7 to 8 weeks, even though washed once a week during that time.

All available DDT is now needed by the armed forces and present production is only sufficient to permit its use as a louse powder.

The efficiency of DDT in combating mite-borne typhus (scrub fever and the like) has not yet been revealed. So far as the classical European typhus is concerned, however, it seems that a phenomenally efficient control procedure is now available.

STREPTOCOCCOSIS

ONE of the most interesting developments of modern medicine is a recognition of the difference between a pathological classification of disease on the one hand and an epidemiological classification on the other. The same germ may produce two quite different clinical disease entities; and the same disease may be caused by quite different etiological agents.

Such a situation has been revealed by recent studies of diseases caused by the hemolytic streptococci. It has been shown that such diverse pathological conditions as scarlet fever, erysipelas, tonsillitis, cervical adenitis and otitis media may be caused by identical or closely related organisms¹; and Sidney Sinclair has suggested the term "streptococcosis" as a useful designation for the entire etiological group.

To avoid a tendency to undue simplification, it should be remembered that other investigators have recorded notable differences between individual streptococcal types in their tendency to produce a particular clinical picture. In a Naval Training Station, it was shown that Types 1 and 6 are generally associated with pharyngitis and tonsillitis, Types 3 and 19, with scarlet fever.²

Nevertheless, it is clear that a single type of streptococcus may—at the same time and in the same family—produce diseases as diverse as scarlet fever, sore throat, erysipelas, and otitis media. Such a situation offers a direct challenge to our conventional practices of isolation and quarantine. A more or less typical state sanitary code provides that scarlet fever shall be isolated for at least 21 days from onset and streptococcus sore throat only during the clinical course of the disease; while erysipelas and otitis media are not mentioned at all. Even our Committee on the Control of Communicable Diseases calls for the isolation of scarlet fever for 21 days "if medical inspection is not available" and for quarantine of exposed children and teachers from association with children and food handlers from their work until 7 days after exposure; while, in the case of septic sore throat, isolation is during the clinical course of disease and convalescence and no quarantine is called for.

It seems somewhat fantastic that of three people in the same family, all infected with the same etiological agent and all equally able to disseminate that agent, one (with a rash) should be isolated for 21 days, one (with a sore throat) during illness, and the third (with a discharging ear) not at all.

The problem is clearly a difficult one. The diagnosis of "scarlet fever" must clearly be maintained for comparability with past statistics, however much or little it means from an epidemiological standpoint. The term "septic sore throat" in our lists of reportable diseases can easily be broadened by adding the words "and other diseases of the upper respiratory tract caused by hemolytic streptococci." Should other forms of streptococcosis also be included in our regulations for isolation and quarantine? Should the isolation period for scarlet fever—as well as for its allied diseases—be based on the disappearance of the causative organisms rather than on an arbitrary time limitation? Are not our present procedures too harsh in the presence of a rash and too lax in its absence?

It seems clear that this subject offers one of the most important challenges to the public health administrator of the future. Streptococcal infections probably rank next after tuberculosis, influenza, pneumonia, syphilis, and "the common cold" in the order of importance of current communicable diseases in temperate climates and in areas of relatively high economic status. We need more intensive

typing studies such as those of Schwentker and his associates; we need expansion of public health laboratory services for the diagnosis and release of streptococcal infections; and we need open-mindedness on the part of administrative and code-making bodies, with a readiness to modify the standard procedures of the past in the light of the new knowledge of the future.

FRIENDS OF THE SLUM

IT has often been pointed out that the social issues involved in our future public health program are more controversial than the earlier problems which related to the control of microbic diseases. "The diphtheria germ has no friends; but the insanitary tenement has powerful allies." The friends of the slum have rallied to its defense during the past year.

The Second Realtors War Conference, the National Association of Real Estate Boards, the National Association of Home Builders, and the United States Savings and Loan League have joined in a concerted attack on public housing which has found its first concrete expression in an organized and heavily financed attack on the National Capital Housing Authority of Washington, D. C.—an assault which has been frankly described as a "pattern" for similar onslaughts on the housing movement throughout the nation. The announced platform of this group is that public housing has been a failure, that no more public housing should be undertaken, and that the housing now controlled by local or federal governmental agencies should be turned over to private enterprise. These champions of the principle of individual initiative are quite willing to have the government buy up the slums at their present inflated values, provided that the land is then turned back to private enterprise. They propose that the needs of the lower income groups be met by means of "rent certificates" issued to individual families through local welfare departments. They state that such certificates must not be used to perpetuate slum conditions; but they do not indicate how such a desirable result can be attained under the plan proposed.

The misrepresentations and fallacies involved in this attack on public housing have been fully and convincingly exposed in Nathan Straus' *Seven Myths of Housing*, reviewed in this issue of the JOURNAL. The strange feature of the situation is that the thinking of this pressure group—presumably representing the considered judgment of business men—moves in a field of sentimental and emotional abstraction and ignores the practical economic facts of the situation.

These facts may be summarized in the form of two main conclusions, both amply verified by economic theory and practical experience. The first of these conclusions is: that no social purpose can be attained by clearing present slums unless and until some other more adequate homes are provided for the present slum dwellers. The health officer knows well that if all the substandard dwellings in a given community were suddenly eliminated, a considerable section of the population would be sleeping in the streets. Therefore, the provision of good homes must go forward hand in hand with the demolition of bad homes.

Second: that the provision of adequate dwellings for the lower income group can only be accomplished by governmental construction of such dwellings for

rental at a figure which the prospective occupants can pay. A substantial proportion of the population—even in 1929, the peak year of peacetime prosperity—had family incomes too low to permit the payment of an economic rent for decent dwelling facilities. Obviously private capital, which rightly and properly operates for a profit, cannot serve this group. Only the people as a whole—actuated by the conviction that decent homes form an essential factor in good citizenship—can fill the gap. It has begun to fill it successfully and economically under the Federal Housing Act of 1937.

The tragic part of this whole controversy is that there is really no conflict at all between public and private housing. Public housing recognizes that at least two-thirds of the homes of the future must and should be built by private capital and that this area of business initiative should be broadened as far as possible by application of new building technologies and sound modern methods of financing. Public housing begins only at the point where private housing is unable to meet our needs.

It is quite possible that the well financed propaganda of the special-interest groups mentioned above will gain local and temporary successes. Of the ultimate triumph of the public housing program we can rest assured. The American people have common sense enough to see that the public purchase and clearing of slum areas, without the provision of adequate housing for the lower income group, can have no effect except to assure speculative real estate owners of profit on swollen urban land values; and that the "rent certificate" can only (as in the past experience of welfare allowances for rent) continue to perpetuate slum conditions; or else provide government grants so large as to cover not only basic costs but also a margin of profit to the entrepreneur; or more probably both. The opponents of public housing object to "concealed subsidies"; but, in effect, they propose new and vast concealed subsidies—to be paid—not to the low-income families who need and deserve aid—but to private real estate interests which are supposed to function on the basis of free competition.

We believe that the vast majority of our fellow-citizens engaged in real estate and allied financial businesses believe in free competition and desire no government aid in the field in which business initiative can function; and that they also recognize the need for government action in the interest of American equality of housing opportunity for the children of those whose economic status does not furnish the possibility of legitimate private profit. They are sadly misrepresented by those of their leaders who are engaged in an attempt to block the progress of a sound and essential public movement and to secure from the public treasury special advantages for the same minorities which have created our present slums and now desire to perpetuate them and recreate them as sources of exploitation.

American Public Health Association

Section Councils

1943-1944

Health Officers Section

(Organized 1908)

- Joseph H. Kinnaman, M.D., *Chairman*, Kay County Health Department, Ponca City, Okla.
Frederick D. Stricker, M.D., *Vice-Chairman*, 816 Oregon Building, Portland, Ore.
Richard F. Boyd, M.D., *Secretary*, 1045 S. Second Street, Springfield, Ill.
Malcolm R. Bow, M.D. (1948)
E. R. Coffey, M.D. (1947)
Earle G. Brown, M.D. (1946)
Adolph Weinzirl, M.D. (1945)
Henry F. Vaughan, Dr.P.H. (1944)

Laboratory Section

(Organized 1899)

- C. A. Perry, Sc.D., *Chairman*, 2411 North Charles Street, Baltimore, Md.
Walter L. Mallmann, Ph.D., *Vice-Chairman*, Michigan State College, East Lansing, Mich.
Edmund K. Kline, Dr.P.H., *Secretary*, Cataugaus County Department of Health, Olean, N. Y.
Pearl L. Kendrick, Sc.D. (1948)
James Gibbard (1947)
Elliott S. Robinson, M.D. (1946)
Harold W. Lyall, Ph.D. (1945)
Thomas F. Sellers, M.D. (1944)

Vital Statistics Section

(Organized 1908)

- Selwyn D. Collins, Ph.D., *Chairman*, U. S. Public Health Service, Washington, D. C.
Thomas J. Duffield, *Vice-Chairman*, 125 Worth Street, New York, N. Y.
Ruth R. Puffer, Dr.P.H., *Secretary*, State Health Department, Nashville, Tenn.
John T. Marshall (1948)
Richard N. Whitfield, M.D. (1947)
Hugo Muench, M.D. (1946)
A. W. Hedrich, Sc.D. (1945)
Thomas W. Chamberlain (1944)

Engineering Section

(Organized 1911)

- Sol Pincus, C.E., *Chairman*, 125 Worth Street, New York, N. Y.
Alfred H. Fletcher, *Vice-Chairman*, 615 North Wolfe Street, Baltimore, Md.

John M. Hepler, C.E., *Secretary*, 320 West Genesee Street, Lansing, Mich.

- A. H. Wieters (1948)
J. Lloyd Barron, C.E. (1947)
Harry B. Hommon (1946)
Earnest Boyce, C.E. (1945)
Roy J. Morton (1944)

Industrial Hygiene Section

(Organized 1914)

- Herbert G. Dyktor, *Chairman*, State Department of Health, Lansing, Mich.
T. Lyle Hazlett, M.D., *Vice-Chairman*, 3509 Fifth Avenue, East Pittsburgh, Pa.
Carl M. Peterson, M.D., *Secretary*, 535 North Dearborn Street, Chicago, Ill.
James G. Townsend, M.D. (1948)
J. J. Bloomfield (1947)
W. J. McConnell, M.D. (1946)
Clarence D. Selby, M.D. (1945)
Charles L. Pool (1944)

Food and Nutrition Section

(Organized 1917)

- Donald K. Tressler, Ph.D., *Chairman*, Stonybrook Road, Westport, Conn.
Marietta Eichelberger, Ph.D., *Vice-Chairman*, 307 North Michigan Avenue, Chicago, Ill.
Marjorie M. Heseltine, *Secretary*, U. S. Children's Bureau, Washington, D. C.
Paul S. Prickett, Ph.D. (1948)
Carl S. Pederson, Ph.D. (1947)
Charles G. King, Ph.D. (1946)
J. O. Clarke (1945)
Harry E. Goresline, Ph.D. (1944)

Maternal and Child Health Section

(Organized 1921)

- Myron E. Wegman, M.D., *Chairman*, 411 East 69th Street, New York, N. Y.
Edythe P. Hershey, M.D., *Vice-Chairman*, State Board of Health, Helena, Mont.
Marion Hotopp, M.D., *Secretary*, State Department of Health, Dover, Del.
Francis V. Corrigan, M.D. (1948)
Hilla Sheriff, M.D. (1947)
Emory Morris, D.D.S. (1946)
Edwin F. Daily, M.D. (1945)
Susan P. Souther, M.D. (1944)

Public Health Education Section

(Organized 1922)

- Mayhew Derryberry, Ph.D., *Chairman*, U. S. Public Health Service, Washington, D. C.
 Lucy S. Morgan, Ph.D., *Vice-Chairman*, University of North Carolina, Chapel Hill, N. C.
 Bruno Gebhard, M.D., *Secretary*, 8811 Euclid Avenue, Cleveland, O.
 Bess Exton (1948)
 J. Louis Neff (1947)
 Thomas G. Hull, Ph.D. (1946)
 Carl A. Wilzbach, M.D. (1945)
 Clair E. Turner, Dr.P.H. (1944)

Public Health Nursing Section

(Organized 1923)

- Marion H. Douglas, R.N., *Chairman*, 57 Forest Street, Hartford, Conn.
 Helene B. Buker, R.N., *Vice-Chairman*, State Department of Health, Lansing, Mich.
 Marian G. Randall, R.N., *Secretary*, 404 E. 55th Street, New York, N. Y.
 Mary D. Forbes, R.N. (1948)
 Dorothy Deming, R.N. (1947)
 Edna L. Moore, R.N. (1946)
 Rena Haig, R.N. (1945)
 Olive Whitlock Klump, R.N. (1944)

Epidemiology Section

(Organized 1929)

- Gaylord W. Anderson, M.D., *Chairman*, 1862 Mintwood Place, N.W., Washington, D. C.
 Franklin H. Top, M.D., *Vice-Chairman*, Herman Kiefer Hospital, Detroit, Mich.

James E. Perkins, M.D., *Secretary*, State Department of Health, Albany, N. Y.

- John J. Phair, M.D. (1948)
 Kenneth F. Maxcy, M.D. (1947)
 Dorothy G. Wiehl (1946)
 W. Lloyd Aycock, M.D. (1945)
 G. Foard McGinnes, M.D. (1944)

School Health Section

(Organized 1942)

- Leona Baumgartner, M.D., *Chairman*, 125 Worth Street, New York, N. Y.
 Harold H. Mitchell, M.D., *Vice-Chairman*, 12-26 31st Avenue, Long Island City, N. Y.
 George M. Wheatley, M.D., *Secretary*, One Madison Avenue, New York, N. Y.
 Ruth E. Grout, Ph.D. (1948)
 Charles J. Prohaska, M.D. (1947)
 Nina B. Lamkin (1946)
 Mary E. Chayer, R.N. (1945)
 N. P. Neilson, Ph.D. (1944)

Dental Health Section

(Organized 1943)

- Kenneth A. Easlick, D.D.S., *Chairman*, University of Michigan, Ann Arbor, Mich.
 J. M. Wisan, D.D.S., *Vice-Chairman*, State Department of Health, Trenton, N. J.
 Walter J. Pelton, D.D.S., *Secretary*, U. S. Public Health Service, Washington, D. C.
 C. R. Taylor, D.D.S., (1948)
 Lester A. Gerlach, D.D.S. (1947)
 George A. Nevitt, D.D.S. (1946)
 Richard C. Leonard, D.D.S. (1945)
 Allen O. Gruebbel, D.D.S. (1944)

American Public Health Association Committees

1943-1944

Committee on Eligibility

Don W. Gudakunst, M.D., *Chairman*, 120 Broadway, New York, N. Y. (1945)
Reginald M. Atwater, M.D., *Secretary*, 1790 Broadway, New York, N. Y.
Helen Bean, R.N., Public Health Nursing Section (1945)
Earnest Boyce, C.E., Engineering Section (1944)
Mary P. Connolly, Public Health Education Section (1944)
William R. Davis, D.D.S., Dental Health Section (1944)
W. Thurber Fales, Sc.D., Vital Statistics Section (1945)
Thomas Francis, Jr., M.D., Epidemiology Section (1944)
Stanley H. Osborn, M.D., Health Officers Section (1945)
Thomas F. Sellers, M.D., Laboratory Section (1944)
Henry T. Scott, Ph.D., Food and Nutrition Section (1944)
David A. Van der Slice, M.D., School Health Section (1945)
Dorothy Worthington, M.D., Maternal and Child Health Section (1945)
William P. Yant, Industrial Hygiene Section (1945)
Elsie A. Siemer, *Associate Secretary*, 1790 Broadway, New York, N. Y.

Committee on Professional Education

William P. Shepard, M.D., *Chairman*, 600 Stockton Street, San Francisco, Calif. (1944)
Reginald M. Atwater, M.D., *Secretary*, 1790 Broadway, New York, N. Y.
Gaylord W. Anderson, M.D. (1944)
W. W. Bauer, M.D. (1944)
Robert D. Defries, M.D. (1945)
Edward S. Godfrey, Jr., M.D. (1945)
Pearl McIver, R.N. (1946)
George H. Ramsey, M.D. (1946)
Lowell J. Reed, Ph.D. (1946)
Wilson G. Smillie, M.D. (1946)
Ernest L. Stebbins, M.D. (1945)
Ralph E. Tarbett, C.E. (1944)
Clair E. Turner, Dr.P.H. (1945)

Consultant:

John Sundwall, M.D.

Isabel Landy Fantel, *Associate Secretary*, 1790 Broadway, New York, N. Y.

Educational Qualifications of Professional Personnel in Sanitation

Ralph E. Tarbett, C.E., *Referee*, U. S. Public Health Service, Washington, D. C.

Educational Qualifications of Health Officers

Ruth R. Puffer, Dr.P.H.
Marian G. Randall, R.N.
John L. Rice, M.D.
Ernest L. Stebbins, M.D.
George M. Wheatley, M.D.

Editorial Board

Reginald M. Atwater, M.D., *Chairman*,
1790 Broadway, New York, N. Y.
Ira V. Hiscock, Sc.D.
Kenneth F. Maxcy, M.D.
Henry E. Meleney, M.D.
Alton S. Pope, M.D.
C.-E. A. Winslow, Dr.P.H.

Editorial Staff

C.-E. A. Winslow, Dr.P.H., *Editor*, Yale
University, New Haven, Conn.
Mazýck P. Ravenel, M.D., *Editor Emeritus*
Reginald M. Atwater, M.D., *Managing
Editor*
Augusta Jay, *Editorial Associate*

Associate Editors:

Leona Baumgartner, M.D.
Martin Frobisher, Jr., Sc.D.
Arthur P. Miller, C.E.
James E. Perkins, M.D.

Resolutions Committee

Huntington Williams, M.D., *Chairman*,
Commissioner of Health, Baltimore, Md.
James B. Black, M.D.
Emilie G. Sargent, R.N.

SECTION COMMITTEES

Laboratory Section

Coördinating Committee on Standard Methods

- A. Parker Hitchens, M.D., *Chairman*, University of Pennsylvania, Philadelphia, Pa.
 Robert S. Breed, Ph.D.
 Thomas Francis, Jr., M.D.
 James Gibbard
 R. A. Kelsner, D.V.M.
 Walter L. Mallmann, Ph.D.
 Friend Lee Mickle, Sc.D.
 Stuart Mudd, M.D.
 Elliott S. Robinson, M.D.
 William D. Stovall, M.D.
 Edmund K. Kline, Dr.P.H. (*ex officio*)
Secretary, Cattaraugus County Department of Health, Olean, N. Y.

Standard Methods Committee on Diagnostic Procedures and Reagents

- William D. Stovall, M.D., *Chairman*, State Laboratory of Hygiene, Madison, Wis.

Referee¹ for:

- Anthrax and Glanders—W. A. Hagan, D.V.M., U. S. Department of Agriculture, Washington, D. C.
 Bacterial Food Poisoning—Gail M. Dack, M.D., University of Chicago, Chicago, Ill.
 Blood Cultures—Casper G. Burn, M.D., Long Island College of Medicine, Brooklyn, N. Y.
 Culture Media, Stains, Reagents and Solutions—A. Parker Hitchens, M.D., University of Pennsylvania, Philadelphia, Pa.
 Gonorrhea and the Gonococcus—Charles M. Carpenter, M.D., University of Rochester, Rochester, N. Y.
 Helminth Parasites and Intestinal Protozoa—Harold W. Brown, M.D., DeLamar Institute of Public Health, New York, N. Y.
 Infectious Mononucleosis—Charles A. Stuart, Ph.D., Brown University, Providence, R. I.
 Laboratory Diagnosis of Diphtheria—Martin Frobisher, Jr., Sc.D., Johns Hopkins University, Baltimore, Md.

Laboratory Diagnosis of Rabies—Thomas F. Sellers, M.D., State Board of Health, Atlanta, Ga.

Laboratory Methods for the Diagnosis of Fungus Diseases—William D. Stovall, M.D., State Laboratory of Hygiene, Madison, Wis.

Lymphogranuloma, Granuloma Venerium, Chancroid—Everett S. Sanderson, M.D., University of Georgia, Augusta, Ga.

Malaria—Aimee Wilcox, National Institute of Health, Memphis, Tenn.

Meningitis and Meningococcus—Sara E. Branham, M.D., National Institute of Health, Bethesda, Md.

Recognition and Significance of Hemolytic Streptococci in Infectious Diseases—Julia M. Coffey, State Department of Health, Albany, N. Y.

Serological and Bacteriological Procedures in the Diagnosis of Enteric Fevers—Marion B. Coleman, State Department of Health, Albany, N. Y.

Serological, Bacteriological and Other Biological Procedures in the Diagnosis of Undulant Fever—A. Parker Hitchens, M.D., University of Pennsylvania, Philadelphia, Pa.

Serological Tests for the Diagnosis of Syphilis—Ruth Gilbert, M.D., State Department of Health, Albany, N. Y.

Studies on the Toxicity of Dyes for Bacteria—Edmund K. Kline, Dr.P.H., Cattaraugus County Department of Health, Olean, N. Y.

The Pneumococcus—Wheelan D. Sutliff, M.D., Department of Health Laboratories, New York, N. Y.

Trichinosis—Lucy S. Heathman, M.D., State Department of Health, Minneapolis, Minn.

Tuberculosis and the Tubercle Bacillus—A. L. MacNabb, D.V.M., Department of Health, Toronto, Ont.

Tularemia—George D. Brigham, Ph.D., Rocky Mt. Laboratory, Hamilton, Mont.

Typhus Fever and Laboratory Methods for Its Recognition—Henry Welch, Ph.D., Food and Drug Administration, Washington, D. C.

Whooping Cough and B. Pertussis—Pearl L. Kendrick, Sc.D., Department of Health Laboratories, Grand Rapids, Mich.

¹ Referees are members of the Standard Methods Committee upon which they serve.

*Associate Referee*² for:

Complement-Fixation Test for Syphilis—
Elizabeth Maltaner, State Department
of Health, Albany, N. Y.

Laboratory Diagnosis of Diphtheria—
Donald T. Fraser, M.B., D.P.H., Uni-
versity of Toronto, Toronto, Ont.

Laboratory Diagnosis of Rabies—Harry
Carnes, M.D., State Board of Health,
Atlanta, Ga.

Laboratory Methods for the Diagnosis
of Fungus Diseases—Lois Almon, Ph.D.,
State Laboratory, Rhineland, Wis.

Studies on the Toxicity of Dyes for Bac-
teria—Cassandra Ritter, Water Labora-
tory, University of Kansas, Lawrence,
Kans.

Tuberculosis and the Tubercle Bacillus—
M. H. Brown, M.D., University of
Toronto, Toronto, Ont.

Typhus Fever and Laboratory Methods
for Its Recognition—Ida A. Bengtson,
Ph.D., National Institute of Health,
Bethesda, Md.

Whooping Cough and B. Pertussis—
George McL. Lawson, M.D., Box 1113,
Charlottesville, Va., and John J. Miller,
Jr., M.D. (Lieutenant Commander),
Naval Base, Navy 717, c/o Fleet
P.O., San Francisco, Calif.

**Standard Methods Committee on Virus
and Rickettsial Diseases**

Thomas Francis, Jr., M.D., *Chairman*, Uni-
versity of Michigan, Ann Arbor, Mich.

**Standard Methods Committee on Exami-
nation of Water and Sewage**

Walter L. Mallmann, Ph.D., *Chairman*,
Michigan State College, East Lansing,
Mich.

*Referee*¹ for:

Bacteriological Methods for Water—Mac
H. McCrady, 89 Notre Dame East,
Montreal, Que.

Chemical Methods for Water—A. M.
Buswell, Ph.D., Water Survey, 57
Chemical Building, Urbana, Ill.

Chemical Methods of Sewage—F. Wellington
Gilcreas, State Department of
Health, Albany, N. Y.

Coliform Group Variants—Leland W.
Parr, Ph.D., George Washington Uni-
versity, Washington, D. C.

Methods for the Determination of Iodine
—John T. Tripp, Ph.D., Army Med-
ical Center, Washington, D. C.

Microscopic Methods of Water—Theodore
A. Olson, 2724 Redick, Omaha, Nebr.

Swimming Pool and Bathing Place
Waters—Walter M. Mallmann, Ph.D.,
Michigan State College, East Lansing,
Mich.

Waterways Pollution—M. Starr Nichols,
Ph.D., State Laboratory of Hygiene,
Madison, Wis.

*Joint Editorial Committee for Standard
Methods for the Examination of Water
and Sewage:*

John F. Norton, Ph.D., *Chairman*, 301
Henrietta Street, Kalamazoo, Mich.

A. M. Buswell, Ph.D., Water Survey, 57
Chemical Building, Urbana, Ill.

W. D. Hatfield, Ph.D., 249 Linden Place,
Decatur, Ill.

H. A. Leverin, Bureau of Mines, Ottawa,
Ont.

Walter L. Mallmann, Ph.D., Michigan State
College, East Lansing, Mich.

M. C. Schwartz, Ph.D., Louisiana State
University, University, La.

**Standard Methods Committee on Exami-
nation of Milk and Milk Products**

Robert S. Breed, Ph.D., *Chairman*, New
York State Agricultural Experiment Sta-
tion, Geneva, N. Y.

Angel de la Garza Brito, M.D., Ave. Alvaro
Obregon No. 190, Mexico City, Mex.

Raoul F. Cowley, Carlos Tercero 1117,
Havana, Cuba

*Referee*¹ for:

Chemical Methods of Examining Dairy
Products—W. A. Queen, Food and Drug
Administration, Washington, D. C.

Comparative Tests of Agar Media for
Standard Milk Work—S. R. Damon,
Ph.D., State Board of Health, Mont-
gomery, Ala.

Coördination of Milk Ordinance and
Laboratory Work—A. W. Fuchs, C.E.,
5420 Connecticut Avenue, Washington,
D. C.

Laboratory Equipment — Raymond V.
Stone, D.V.M., 808 North Spring Street,
Los Angeles, Calif.

Methods of Counting Bacteria in Dairy
Products—A. H. Robertson, Ph.D.,
State Department of Agriculture and
Markets, Albany, N. Y.

¹ Referees are members of the Standard Methods
Committee upon which they serve.

² Associate Referees are not members of the Stand-
ard Methods Committee upon which they serve.

Methods for Detecting Organisms of the Coliform Group—A. J. Slack, M.D., Institute of Public Health, London, Ont.

Methods of Isolating Specific Types of Bacteria in Dairy Products—Mac II. McCrady, 89 Notre Dame East, Montreal, Que.

Methylene Blue Reduction Test—C. A. Abele, Ch.E., Director, County Dairy Inspection Section, Board of Health, Chicago, Ill.

Microbiological Methods for Examining Butter—Harold C. Olson, Ph.D., Oklahoma Agricultural and Mechanical College, Stillwater, Okla.

Sediment Test—E. H. Parfitt, Ph.D., 307 North Michigan Avenue, Chicago, Ill.

Tests for the Sterility of Dairy Utensils—Walter D. Tiedeman, M.C.E., State Department of Health, Albany, N. Y.

Associate Referee² for:

Methods for the Examination of Cheese—M. W. Yale, Ph.D., 1150 South Webster Avenue, Green Bay, Wis.

Methods of Examining Milk for Evidences of Brucella Infection—I. F. Huddleson, Ph.D., Michigan State College, East Lansing, Mich.

Methods of Examining Milk for Tubercle Bacilli—William A. Hagan, D.V.M., U. S. Department of Agriculture, Washington, D. C.

Methods of Identifying Streptococci in Dairy Products—George J. Hucker, Ph.D., New York State Agricultural Experiment Station, Geneva, N. Y.

Phosphatase Test—J. H. Shrader, Ph.D., Eastern Nazarene College, Wollaston, Mass.

Resazurin Test—C. K. Johns, Ph.D., Central Experimental Farm, Ottawa, Ont.

Subcommittee on Methylene Blue Reduction and Resazurin Tests:

C. A. Abele, Ch.E., *Chairman*, Director, Country Dairy Inspection Section, Board of Health, Chicago, Ill.

W. D. Dotterrer, 140 West Ontario Street, Chicago, Ill.

C. K. Johns, Ph.D., Central Experimental Farm, Ottawa, Ont.

E. H. Parfitt, Ph.D., 307 No. Michigan Avenue, Chicago, Ill.

A. H. Robertson, Ph.D., State Depart-

ment of Agriculture and Markets, Albany, N. Y.

H. R. Thornton, Ph.D., University of Alberta, Edmonton, Alta.

Subcommittee on Sediment Testing:

E. H. Parfitt, Ph.D., *Chairman*, 307 North Michigan Avenue, Chicago, Ill.

J. O. Clarke, U. S. Food and Drug Administration, Chicago, Ill.

K. G. Weckel, Ph.D., University of Wisconsin, Madison, Wis.

Joint Editorial Committee for Standard Methods for the Examination of Dairy Products:

Robert S. Breed, Ph.D., *Chairman*, New York State Agricultural Experiment Station, Geneva, N. Y.

E. M. Bailey, Ph.D., New Haven Agricultural Experiment Station, New Haven, Conn.

A. Parker Hitchens, M.D., University of Pennsylvania, Philadelphia, Pa.

Friend Lee Mickle, Sc.D., State Department of Health, Hartford, Conn.

Henry T. Scott, Ph.D., Wisconsin Alumni Research Foundation, Madison, Wis.

Standard Methods Committee on Biology of the Laboratory Animal

R. A. Kelser, D.V.M.,* *Chairman*, Office of Surgeon General, U. S. Army, Washington, D. C.

Paul A. Moody, Ph.D., *Acting Chairman*, University of Vermont, Burlington, Vt.

Associate Referees²

Arthur M. Cloudman, Ph.D., Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Me.

R. G. Daggs, Ph.D., University of Vermont, Burlington, Vt.

Ralph W. Mohri, D.V.M., Army Medical Center, Washington, D. C.

Gregory Pincus, D.Sc., Clark University, Worcester, Mass.

Norman J. Pyle, V.M.D., 335 W. Barnard Street, West Chester, Pa.

Paul B. Swain, Sc.D., Brown University, Providence, R. I.

George B. Wislocki, M.D., Harvard University Medical School, Boston, Mass.

Standard Methods Committee for Frozen Desserts and Ingredients (Joint with the Committee of Food and Nutrition Section)

² Associate Referees are not members of the Standard Methods Committee upon which they serve.

* In Active Military Service

Friend Lee Mickle, Sc.D., *Chairman*, State Department of Health, Hartford, Conn.
James Gibbard, Department of Pensions and National Health, Ottawa, Ont.

Referee¹ for:

Chemical Analysis of Frozen Desserts and Ingredients—J. H. Shrader, Ph.D., Eastern Nazarene College, Wollaston, Mass.
Microbiological Examination of Frozen Desserts—A. H. Robertson, Ph.D., State Department of Agriculture and Markets, Albany, N. Y.
Microbiological Examination of Ingredients—F. W. Fabian, Ph.D., Michigan State College, East Lansing, Mich.
Sediment Testing of Frozen Desserts and Ingredients—Milton E. Parker, 1526 S. State Street, Chicago, Ill.

Associate Referee² for:

Chemical Determinations of Modified Babcock Methods for Frozen Desserts—W. H. Martin, Kansas State College, Manhattan, Kans.
Chemical Determinations for Phosphatase Test for Frozen Desserts—George Jaggard, 1037 Park Avenue, Collingswood, N. J.
Chemical Determinations of Stabilizers in Frozen Desserts—F. Leslie Hart, Food and Drug Administration, San Francisco, Calif.
Determination of Overrun in Ice Cream—P. S. Lucas, Michigan State College, East Lansing, Mich.
Microbiological Examination of Condensed and Evaporated Milk—Paul A. Downs, Ph.D., University of Nebraska, Lincoln, Nebr.
Microbiological Examination of Dry Milk—Paul S. Prickett, Ph.D., Evansville, Ind.
Microbiological Examination of Eggs—M. Thomas Bartram, Ph.D., Food and Drug Administration, Washington, D. C.
Microbiological Examination of Flavors, Colors, Fruits and Nuts—M. J. Prucha, Ph.D., University of Illinois, Urbana, Ill.
Microbiological Examination of Sugar—H. H. Hall, Southern Regional Research Laboratory, New Orleans, La.

Sampling for Chemical Determinations—P. H. Tracy, Ph.D., University of Illinois, Urbana, Ill.
Sediment Testing of Concentrated and Dried Milks—E. C. Thompson, Ph.D., 350 Madison Avenue, New York, N. Y.
Sediment Testing of Egg Products—Bernard E. Proctor, Ph.D., Office of Quartermaster General, U. S. Army, Washington, D. C.

Standard Methods Committee on Biological Products

Elliott S. Robinson, M.D.,* *Chairman*, 1321 Holly Street, N.W., Washington, D. C.
Harold W. Lyall, Ph.D., *Acting Chairman*, New York State Department of Health, Albany, N. Y.
George D. W. Cameron, M.D., Dominion Department of Health, Ottawa, Ont.
Robert D. Defries, M.D., 5 Cluny Drive, Toronto, Ont.
Ralph S. Muckenfuss, M.D., 26 East 11th Street, New York, N. Y.
John T. Tripp, Ph.D., Army Medical Center, Washington, D. C.
Milton V. Veldee, M.D., National Institute of Health, Bethesda, Md.

Standard Methods Committee for Examination of Shellfish

James Gibbard, *Chairman*, Department of Pensions and National Health, Ottawa, Ont.
C. T. Butterfield, Principal Bacteriologist, U. S. Public Health Service, Cincinnati, O.
A. C. Hunter, Ph.D., Food and Drug Administration, Washington, D. C.
C. B. Kelly, Jr., New York State Conservation Department, Freeport, L. I., N. Y.
C. A. Perry, Sc.D., State Department of Health, Baltimore, Md.
Leslie A. Sandholzer, Ph.D., Technological Laboratory, Fish and Wildlife Service, College Park, Md.
Hermann Sommer, Ph.D., Hooper Foundation, University of California Medical Center, San Francisco, Calif.
F. W. Tanner, Ph.D., University of Illinois, Urbana, Ill.

Standard Methods Committee for the Examination of Germicides and Antibacterial Agents

Stuart Mudd, M.D., *Chairman*, University of Pennsylvania, Philadelphia, Pa.

¹ Referees are members of the Standard Methods Committee upon which they serve.

² Associate Referees are not members of the Standard Methods Committee upon which they serve.

* In Active Military Service.

Referee¹ for:

Chemical Antiseptics — Henry Welch,
Ph.D., Food and Drug Administration,
Washington, D. C.

Chemical Disinfectants — Charles M.
Brewer, U. S. Department of Agriculture,
Beltsville, Md.

Detergents—Walter L. Mallmann, Ph.D.,
Michigan State College, East Lansing,
Mich.

National Institute of Health, Bethesda,
Md.

Fungicidal and Fungistatic Agents—C. W.
Emmons, Ph.D., National Institute of
Health, Bethesda, Md.

Laboratory Section Archivist

Anna M. Sexton, State Department of
Health, Albany, N. Y.

Associate Referee² for:

Antibiotic Agents—Selman A. Waksman,
Ph.D., Agricultural Experiment Station,
New Brunswick, N. J.

Disinfection of Air by Germicidal Vapors
and Mists—O. H. Robertson, M.D.,
University of Chicago, Chicago, Ill.

Disinfection of Air by Ultraviolet Irradia-
tion — Alexander Hollaender, Ph.D.,

**Laboratory Section Representative on the
Commission for the Study of Bio-
logical Stains**

William D. Stovall, M.D., State Laboratory
of Hygiene, Madison, Wis.

¹ Referees are members of the Standard Methods
Committee upon which they serve.

² Associate Referees are not members of the Stand-
ard Methods Committee upon which they serve.

BOOKS AND REPORTS

The Seven Myths of Housing—
By Nathan Straus. New York: Knopf,
1944. 320 pp. Price, \$2.75.

Mr. Nathan Straus, a life-long friend of housing, who has served as member of the New York City Housing Authority and as Administrator of the United States Housing Authority, has prepared a distillate of his long experience in a form which is particularly timely and important at the present moment. The "Seven Myths of Housing" which he discusses are as follows:

1. "There are no slums in my town"; every health officer knows the answer to this one.

2. "Public housing does not clear slums"; during the first four years of our federal housing program more than 78,000 unsafe or insanitary dwellings were eliminated, about half on the site of new projects and about half in accordance with the law which calls for the elimination of an equivalent number of substandard dwellings when a new housing project is built on relatively unoccupied land.

3. "The government should buy up the slums"; the elimination of existing slums without providing new housing within the means of slum tenants might be very profitable to the real estate interests, but would in no sense improve the housing of the people. Only the construction of new low-rent homes will make the elimination of slums socially possible.

4. "Public housing is costly and extravagant"; the actual construction of the United States Housing Authority homes has cost one-quarter less than the average cost of similar housing produced by private enterprise. Mr. Straus gives an admirable analysis of the various factors which enter into rent, in-

cluding actual construction costs, costs of dwelling equipment, architects' fees and overhead charges, cost of land, cost of utilities, taxes, operation, and upkeep.

5. "Public housing does not rehouse families from the slums"; that this is untrue is indicated by the fact that over 90 per cent of the families in public housing projects have family incomes of less than \$1,200, which indicates that without federal aid they cannot live anywhere except in the slums.

6. "The slum dweller creates the slums"; experience in housing management fully demonstrates the fallacy of this assumption.

7. "Public housing injures private business and threatens to bankrupt the country"; public housing cannot injure private business, since no tenant is admitted unless his income is too low to purchase housing for an economic rent and unless he is living in an insanitary and substandard dwelling; a comprehensive and effective public housing program has not "bankrupted" England or Holland or Sweden, and it is not likely to "bankrupt" us.

Mr. Straus outlines a post-war goal of 900,000 new dwellings a year, of which about one-third should be low-rent housing provided by government subsidy, the other two-thirds to be built by private enterprise, with some government assistance in the middle income groups.

This is by all odds the best book on the philosophy of public housing now available. It should be on the desk of every health officer or other public health worker who wishes to be prepared to take an intelligent stand in regard to this vital health issue of the future.

C.-E. A. WINSLOW

Civilization and Disease — By Henry E. Sigerist. Ithaca, N. Y.: Cornell University Press, 1943. 255 pp. Price, \$3.75.

This book is an excellent illustration of the thesis stated by Dr. Sigerist as follows:

The historian is a member of the society in which he lives, sharing its hopes and fears, its aspirations and frustrations. Driven by a burning interest, by an overpowering urge, he sets out to consult the past—not the past at large, but a certain period, a sequence of events, personalities or problems. He wants to know what things were like, and to this end he assembles all the documents he can find. They become sources to him; he questions them, makes them talk, tries to understand and interpret them. Gradually a period, events, people of the past long dead become alive to him, an experience which he wants to share with others through the living word and in literary form. He recreates the past and by so doing makes the writing of history an artistic process.

In the present volume he discusses such subjects as civilization as a factor in the genesis of disease, and the inter-relationships of disease with history, economics, law, religion, philosophy, science, literature, art and music.

In reading the present volume one has the sensation of sitting before an open fire with a pipe or a cigar and a decanter of port, listening to the conversation of a charming companion full of ancient lore and modern wisdom. The fascinating illustrations from medieval sources add greatly to its interest.

The health officer may question whether masks really proved effective during the influenza epidemic of 1918–1919 and might object to the statement that “since organic material decomposes it provides breeding ground for parasites which are a menace to man.” To some of us it seems strange that Fracastorius and Kircher are not mentioned in connection with the history of the germ theory of disease, and that Sanctorius does not find place with

Harvey among the pioneers in experimental physiology.

These would, however, be merely carping criticisms of a sound and scholarly and fascinating work. It is not intended as a textbook and it does not follow any special logical order, but there is a connecting link through nearly all the chapters, in Dr. Sigerist's emphasis upon the fact that

... the task of medicine is to promote health, to prevent disease, to treat the sick when prevention has broken down and to rehabilitate the people after they have been cured. These are highly social functions and we must look at medicine as basically a social science. Medicine is merely one link in a chain of social welfare institutions that every civilized country must develop. If we have a maladjustment today, it is to a large extent due to the fact that we have neglected the sociology of medicine. For a long time we concentrated our efforts on scientific research and assumed that the application of its results would take care of itself. It did not, and the technology of medicine has outrun its sociology.

The closing paragraph of the epilogue which refers to the present world crisis is heartening:

The more I study history, the more faith I have in the future of mankind, and the less doubt as to the ultimate result of the present conflict. The step will be taken from the competitive to the coöperative society, democratically ruled on scientific principles, to a society in which all will have equal duties and equal rights, not only on paper but in fact. We may not see it, but our children or their children will. While we are struggling, the foundations are being laid for a new and better civilization.

C.-E. A. WINSLOW

Twenty Years of Medical Research—By Dorothy White Nicolson. New York: National Tuberculosis Association, 1943. 97 pp. Price, \$.50.

Nowhere has medical research taken a more varied pattern than in these United States during the past forty years, and at no time since the “Golden Age of Bacteriology” has the development of basic scientific knowl-

edge been more rapid. Though a majority of the outstanding contributions have been the work of talented individuals, often working independently, the growing complexity of the natural sciences has inevitably led to an increasing interdependence of investigators. It was recognition of the need of utilizing the resources of the allied sciences, as well as those of medicine, in broadening our basic knowledge of tuberculosis, that governed the Committee on Medical Research of the National Tuberculosis Association in determining its policy in 1920. This policy has been to encourage and assist a few investigators whose work promised to bridge to some extent an existing gap in our knowledge of tuberculosis or to provide more effective methods of diagnosis or treatment.

How wide a field has been covered by the researches of the following twenty years is indicated by a list of 21 projects supported by 35 grants. The projects have covered such diverse fields as Snow's classical study on the "Anatomy of the Lungs," coöperative studies on the chemistry of the tubercle bacillus and improvements in x-ray technic. That the results of the studies sponsored by this Medical Research Committee rank among the leading contributions to our knowledge of tuberculosis during the past two decades will be generally recognized by tuberculosis workers. Perhaps an even greater contribution is the demonstration of the possibilities of coöordinated effort among investigators in medical science, for only by such coöperation can the necessary knowledges and technics of modern science be brought to bear upon a given problem. The effective application of this method calls for long-time planning and over-all supervision, and credit for the accomplishments of the National Tuberculosis Association's research program belongs in no small part to the Research Committee who, under the

continued chairmanship of Dr. William Charles White, has encouraged and directed the twenty years of effort. For the student of tuberculosis the detailed bibliography gives convenient access to all individual reports of investigations associated with the committee's research program. ALTON S. POPE

Administration of Relief Abroad—A Series of Occasional Papers, Edited by Donald S. Howard, Russell Sage Foundation (130 East 22nd Street, New York 10). Price, \$.20 each, or \$1.50 for the set of eight.

The Near East Relief, 1915-1930, by James L. Barton.

The American Red Cross in the Great War, 1917-1919, by Henry P. Davison.

American Aid to Germany, 1918-1925, by Sidney Brooks. Together with *The Long Mile Beyond Berlin*, by Shelby M. Harrison.

The American Friends Service Committee in France, 1917-1919, by Rufus M. Jones. Together with *Problems Involved in Administering Relief Abroad*, by Clarence E. Pickett.

The American Relief Administration in Russia, 1919-1925, by H. H. Fisher.

Recent Operations of the American Friends Service Committee in Spain and France: Operations in Spain, 1937-1939, by John Van Gelder Forbes. *Operations in France, 1941-1942*, by the American Friends Service Committee.

American Red Cross Famine Relief in China, 1920-1921, from the Report of the China Famine Relief, American Red Cross.

Foreign Relief and Rehabilitation—A Bibliography, compiled by Sigrid Holt.

There was a world war twenty-five years ago which was widespread and terrible enough at the time. The

sympathy and funds of this country were poured out in efforts to repair some of the damage to human beings. Smaller disasters since have met with like response. The seven books listed were, fortunately, published by the different groups to inform the public who had supported the work.

Today suffering even more widespread is calling for plans for immediate and post-war relief. Effective administration is essential. Those who will share in this work, either in planning or in the field, will find these booklets very valuable.

They are case records. Each is a digest of the book abstracted, in one-tenth the size, using a current technic. Together they enable the reader to study the widely varied methods of the different groups, and profit by their experiences. With them should be read the report of the Atlantic City conference of the United Nations last fall. A new framework is appearing.

Clarence E. Pickett's remarks, at the close of Rufus M. Jones's book, combine sound views with a sense of the spirit that quickeneth.

One question comes to the reviewer. If height-weight tables are now out, what tool will the workers in nutrition give us today with which to select children for special feeding?

Perhaps the Russell Sage Foundation will add to our debt by binding this "First Series" under one cover.

HENRY R. O'BRIEN

Orthopedic Nursing—By Robert V. Funsten, M.D., and Carmelita Calderwood, R.N., A.B. St. Louis: Mosby, 1943. 602 pp. Price, \$3.75.

This volume represents an approach to combined medical and nursing consideration of the care of patients with orthopedic conditions. It is presented by a physician and a nurse in a manner which will meet a long felt need of the nursing profession.

The introductory unit emphasizes the need for clearer understanding of the orthopedic content of all types of illness, as well as the relationship between body mechanics and posture and the efficiency of normal activity. In the second unit are grouped several chapters dealing with nursing care of cast and surgical patients, description and explanation of the use of orthopedic linens and restraints, and a general discussion of the responsibility of nursing in relation to physical therapy service.

The remainder of the book is divided into units in each of which related orthopedic conditions are grouped. The authors give excellent support to each other in presenting from the medical standpoint information necessary to the intelligent nursing care of orthopedic conditions, and from the nursing standpoint procedures necessary to the successful outcome of medical or surgical care instituted by the physician. Throughout the discussion of nursing responsibility emphasis is placed upon prevention and the part the nurse may play in this.

Orthopedic Nursing should prove valuable to both institutional and public health nurses giving care to orthopedic patients, and to all nurses who are interested in reducing the volume of preventable disabilities.

FLORENCE L. PHENIX

An Introduction to Foods and Nutrition—By Henry C. Sherman and C. S. Lanford. New York: Macmillan, 1943. 292 pp. Price, \$2.00.

This book is a simple textbook on nutrition. It attempts: "first, to indicate the personal and public importance of the present-day knowledge of nutrition; second, to summarize with the greatest possible clarity and conciseness the needs of normal nutrition in terms of the accepted 'yardstick'; third, to introduce in an adequate manner the articles and types of food through which

our nutritional goals are to be reached; and finally to make this unified knowledge of foods and nutrition a functional part of household management and of family life and thought." Appendix A gives the approximate average nutritive values of 100 g. (edible portion) of several more common foods; appendix B is a simple glossary.

This book can be understood by anyone interested in nutrition. It is the simplest of Dr. Sherman's texts on nutrition but maintains the same high standards of his previous books.

FREDRICK J. STARE

Heart Disease Is Curable—*By Peter J. Steincrohn, M.D. New York: Doubleday Doran, 1943. 193 pp. Price, \$1.98.*

The great advances being made by medicine and allied sciences have created a growing demand for popular books on specific diseases and their cure. It is only natural that people are curious about heart diseases, for they rank high as killers and make invalids of millions. The author of *Heart Disease Is Curable* has set himself the task of enabling people to satisfy their curiosity by writing a readable volume on the subject.

Many cardiologists and public health workers may be surprised by the title of the book, and justly so. While Dr. Steincrohn's text is consistent with his own definition of "curable," the phrase is misleading, since at the present time most diseases of the heart are not "curable" in the generally accepted sense of that word. It is also questionable as to what extent a book designed for the average layman should go into technical matters of diagnosis and treatment. For instance, in Chapter VII methods of treatment are presented which do not apply to all cardiac patients—"Sodium salt is eliminated from the diet as this tends to keep fluid in the tissues." Such instructions are

not properly the content of a book for popular consumption. The author's recommendations in regard to frequent periods of rest and retiring from gainful activity are not possible except for those in the upper economic brackets, and at times may not be possible for them. There is no recognition of the difficult economic problem faced by the average wage earner with heart disease.

The psychological approach of the book is good. It places the patient in a happy frame of mind, particularly Chapter II, "Your Doctor Is Not a Bogeyman," and Chapters IX and XIII which, if condensed, would make a good pamphlet on heart disease.

DAVID D. RUTSTEIN

Biochemistry of the Fatty Acids.
—*By W. R. Bloor. New York: Reinhold, 1943. 387 pp. Price, \$6.00.*

The subject of this book is indicated by the following quotation from page 286: "The whole of our knowledge (of the subject matter of the book) at present constitutes a picture puzzle of which only a few parts are available. Nevertheless, it is interesting and instructive to try to fit these parts together to get some idea of what the complete picture might be."

The greater part of the book is a scholarly and soberly critical summary of the enormous literature (about 1,770 citations) of which the above "few parts" are composed. Otherwise the book consists of stimulating interpretations which verify the correctness of the second sentence in the above quotation.

The composition of the book is indicated more specifically by its chapter headings, of which there are six as follows:

1. Chemistry: Descriptive and Analytical
2. Digestion and Absorption
3. Lipids of the Blood
4. The Lipids in Tissue
5. Lipid Metabolism
6. The Lipids of Secretions and Excretions

The book was apparently written for biochemists and physiologists rather than for clinicians or for commercial fat and oil technologists. However, members of all of these professions will find the book interesting, stimulating, and helpful.

Congratulations are due to the author for his excellent English, which adds to the readability and usefulness of the Book.

O. S. RASK

Health Instruction Yearbook, 1943
—*Compiled by Oliver E. Byrd, Ed.D.*
Foreword by Ray Lyman Wilbur, M.D.
Stanford University: Stanford University Press, 1943. 308 pp. Price, \$3.00.

This yearbook is the first venture in what is intended to be a new project, namely, annual preparation of such books. The book is divided into twenty chapters which deal, respectively, with health as a social accomplishment; health as a social problem; nutrition and health; excretion and health; exercise and body mechanics; fatigue and rest; mental health and disease; heredity and eugenics; infection and immunity; chronic and degenerative disorders; habit-forming substances; the care of special organs; safety; health and physical environment; health services and facilities; family health; school health; occupational health; community health services, trends and probabilities.

The book is composed of brief excerpts taken from a wide variety of sources and grouped in chapters under the topic headings already listed. Taking Chapter VII, on Mental Health and Disease as an example, one finds in this chapter an item on national morale; one on war service and mental hygiene of the young-age group; another on mental health and the war in Germany and Britain; one on mental health and military service in the United States; one on a new type of

homesickness encountered in the Navy; one on war fears in soldiers; a Census Bureau estimate of the number of patients in mental hospitals in the United States; some material on psychological weapons of war; a Census Bureau report on suicides in the United States and one on killings in America; an article on recreation and mental health, and one on mental hygiene in industry.

Each of the items is numbered, beginning with 1 and ending with 300 at the end of the last chapter. Bibliographical references are grouped at the end, which causes an endless amount of paging back and forth when these sources could have been listed just as well in immediate juxtaposition to the item.

Regardless of minor defects in the present volume, it represents a worthwhile endeavor and one which public health workers, especially those in health education, might hope to see continued year by year. Necessarily it is a collection of miscellany, but such a collection if well selected can be of the utmost value, since it may become a repository for the hard-to-find items which every health educator needs to enliven his material and which so often remain elusively just outside of memory's grasp.

In subsequent editions, however, it would seem that a better dating should be placed upon the book. This book is dated 1943, yet it was published in October and must have been compiled early in the year. Most of the references bear a 1942 date and a few are dated in 1941. This is really a 1942 yearbook issued in 1943. Before the series is any older this matter of dating should be rectified.

As for the author's judgment in selecting items for inclusion, that is hardly subject to criticism, since it is his judgment, which some readers will approve and others will disapprove. It will always be so.

As a source book this volume, especially if the series is continued as proposed, should find a place in every health educator's library.

W. W. BAUER

Notable Contributions to the Knowledge of Syphilis—By *Herman Goodman, M.D.* (*First Limited Edition.*) New York: Froben Press, 1943. 144 pp. Price, \$3.00.

The author's introduction to the book is entitled "The Development of Medical Science Stressing Knowledge of Syphilis," which is a more appropriate title. Many of the pre-Columbian personalities mentioned were not notable contributors to the knowledge of syphilis but their names are linked in a long chronological chain which "gives the narrative much of its fascination," to quote Dr. Victor Robinson who wrote the foreword.

The author has performed a real service in recording, in one volume of 144 pages, so many data on the historical aspects of our knowledge of syphilis. Conclusions by the author are rightly omitted; each reader can make a more detailed study of the material cited for whatever purpose he has in mind.

Contemporary contributors to the knowledge of syphilis are merely listed by name, in the very complete Index of 720 names.

The assembly of the illustrations and preparation of the biographical and other data, as well as the citing of references to more complete discussion of various phases of the knowledge of syphilis, has been a task of great magnitude. The 143 illustrations are photographs or pre-photographic era drawings of the persons mentioned. Only two or three of those represented by pictures are now living.

The volume is useful as a source or

reference book for libraries, and anyone interested in the historical phases of the development of the present knowledge of syphilis.

C. C. PIERCE

Nurses' Handbook of Obstetrics—By *Louise Zabriskie, R.N., and Nicholson J. Eastman, M.D.* (*New 7th Ed.*) Philadelphia: Lippincott, 1943. 714 pp. Price, \$3.25.

The seventh edition of this textbook, completely revised and newly illustrated, comes at an opportune moment when our birth rate is high and mothers who were never able to afford hospital deliveries or skilled nursing care at home are now able to pay for the best. Nurses are attending more deliveries than in 1935. They are looking for the best and newest knowledge of maternity care and will find in this textbook a satisfactory source of information, as it combines, skillfully and smoothly, the field of public health, institutional and home care, with attention paid to teaching through classes, health educational material, and individual conferences. Teachers will find the material already organized for unit instruction, and for the older nurse who wishes to brush off her dusty knowledge of obstetrics—here is the book, with questions for self-examination which reveal the depth of that dust!

A book in its seventh (revised) edition grows richer with age or, to use another simile, cream rises on standing. While no one textbook ever claims perfection and no real student (or teacher) is ever satisfied with a sole source of information on any subject, this textbook shows the effect of many constructive suggestions and reëditing. It is now as comprehensive a reference as a nurse—any nurse—could hope to find in a single volume.

DOROTHY DEMING

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Let's Have More Safe Milk—As part of a public works program the suggestion is made that new municipal pasteurizing plants, and additions to present ones, to the tune of \$8,000,000—not counting country pasteurizers—would prevent a lot of milk-borne disease, increase milk consumption, and help get people back to work. Small change, these days, but an important expenditure, for there were 408 milk-borne epidemics involving 16,000 cases in a recent decade.

ANDREWS, J., and FUCHS, A. W. National Inventory of Needs for Sanitation Facilities. Pub. Health Rep. 59, 6:189 (Feb. 11), 1944.

And Safer Drinking Water—Prepared by the Public Health Service, this manual is for the guidance of local health officials to secure greater uniformity and safety in the control of water supplies.

ANON. Sanitation Manual for Public Ground Water Supplies. Pub. Health Rep. 59, 5:139 (Feb. 4), 1944.

Here's a Brave Man for You—Direct treatment of the teeth with fluoride-containing solutions will reduce dental caries. Probably this is a better method than adding fluorine to public water supplies, concludes the writer who adds without any face-saving qualification, "The immediate possibilities for the control of caries are extremely bright."

BIBBY, B. G. Use of Fluorine in the Prevention of Dental Caries. J. Am. Dent. A. 31, 3:228 (Feb. 1), 1944.

New Ideas Department—For a rank layman to annotate a paper of which he understands not a quarter

of the words is the height of something or other, but here goes: It seems you take some spleen and rib marrow of a fresh human cadaver, grind the tissues and dry them. This antigen is diluted and injected into animals, much as we do to obtain antibacterial sera. The titer of cytotoxins is determined by complement-fixation. In small doses this anti-reticular cytotoxic serum stimulates the connective tissues of the body to intensify active immunity against all sorts of infections.

BOGOMOLETS, A. A. Anti-Reticular Cytotoxic Serum as a Means of Pathogenic Therapy. (and) MARCHUK, P. D. A Method of Preparing and Preserving Anti-Reticular Cytotoxic Serum. Am. Rev. Soviet Med. 1, 2:101 (Dec.), 1943.

Present-day Pneumonia Experience—Among 90,000 shipyard workers in 1943 there was a pneumonia frequency rate of 9.5 per 1,000. Of 864 patients over 70 per cent had pneumococcal pneumonia. For some of these patients, both serum and sulfonamides were given, the gross mortality being 8.2 per cent.

COLLEN, M. F., *et al.* A Study of Pneumonia in the Shipbuilding Industry. J. Indust. Hyg. & Toxicol. 26, 1:1 (Jan.), 1944.

Had This Occurred to You?—When birth rates vary considerably, the infant death rates, as ordinarily computed, may be no longer accurate, for many infant deaths will be from among babies born during the previous year. Hence a rapidly declining birth rate may produce a fictitiously high infant death rate. This paper suggests how corrective adjustments may be made.

DE PORTE, J. V. Rate of Infant Mortality Adjusted to a Rapidly Changing Birth Rate. *Health News (New York State)*. 21, 5:20 (Jan. 31), 1944.

How Many Have Cancer and What Kinds?—About 4 of every 1,000 city dwelling Americans have, or have had, cancer. About a half million people are under treatment for cancer at any given time, 300,000 new cases being diagnosed each year. Case rates are higher among women and, in both sexes, increase each decade of life. In almost half the males and three-quarters of the females, cancer occurs in either the digestive or genital systems. These are only a few of the arresting answers to our questions.

DORN, H. F. Illness from Cancer in the United States. *Pub. Health Rep.* (beginning). 59, 2:33 (Jan. 14), 1944.

Care for the Needy Sick—New York State has worked out a practical pattern of public medical care for the needy which supplants archaic "poor doctor" practices, places medical men in charge of medical aspects, and builds a whole new approach to government-physician relationships, in some respects, out-Beveridging the Beveridge plan itself.

DOWLING, L. C. New York State Public Medical Care Program. *Pub. Welfare*. 2, 2:44 (Feb.), 1944.

Strep Types and Scarlet Fever—All epidemiologists who may be struggling with the problem of controlling streptococcal infections will be interested in the findings of this army experience in which soldiers with pharyngitis-tonsillitis were hospitalized regardless of existence or nonexistence of scarlatiniform rashes. The study of streptococcal types is most revealing.

HAMBURGER, M., JR., *et al.* Ability of Different Types of Hemolytic Streptococci to Produce Scarlet Fever. *J.A.M.A.* 124, 9:564 (Feb. 26), 1944.

Health Service vs. Medical Practice—Why did you join the local health services? a British M. O. H. asked his colleagues. Nearly half said they joined because of their interest in some specialty. Also nearly half liked the idea of regular hours and fixed salary. A fifth had tried general practice and didn't like it, and 43 per cent believed that they could best serve the community through preventive medicine. A comparative poll of American health officers might produce illuminating comparisons.

JOLLY, R. H. H. The Public Health Service after the War. *Pub. Health*. 57, 4:39 (Jan.), 1944.

This Paper Is about the Blue Cross—Sanitary engineers, chemists, bacteriologists, inspectors, and educators will view with some curiosity the following resounding and unqualified declaration, "American medicine, American dentistry, American nursing, and American hospitals have given our people the world's finest health service. With respect to education, service, and research, American health service has reached a degree of perfection never realized in any other country on earth." The theme of the peroration is: Everybody in the Blue Cross by 1960.

MANNIX, J. R. Voluntary Non Profit Payment for Health Care. *J.A.M.A.* 124, 9:571 (Feb. 26), 1944.

They Are Still Being Born One a Minute—Medical departments in five industrial plants, widely scattered, conducted a large scale demonstration of the value of cold vaccines, of all sorts, and found no evidence of effective prophylaxis against the frequency or the severity (including complications) of colds. Do you suppose this experience will have any influence upon the makers, the givers, or the gullible receivers of cold vaccines?

McGEE, L. C., *et al.* "Cold Vaccines" and

the Incidence of the Common Cold. J.A.M.A. 124, 9:555 (Feb. 26), 1944.

One State Is Awake at Any Rate—Brave new plans for an ambitious health and welfare service for the State of Maine should serve to inspire similar agencies to bestir themselves to do something to anticipate post-war health problems in the other 47 states.

PAGE, H. O. Preliminary Statement on Post-war Planning in Health and Welfare. Pub. Welfare. 2, 2:36 (Feb.), 1944.

A Desire to Save Babies Is Needed—Methods employed by the city of Chicago to reduce neonatal deaths are described. Adequate care for premature infants, better obstetrical practice, prevention of infection are the chief infant life saving measures. If they were employed throughout the nation 40 per cent of all infant deaths

might be prevented. Three additional papers by Sage, E. C., Torpin, R., and Tyson, R. M., complete this timely and useful symposium. Child hygienists won't neglect this series; many others of us should not.

POTTER, E. L. The Lesson to Be Learned from a Study of Infant Deaths. J.A.M.A. 124, 6:336 (Feb. 5), 1944.

Health for War Workers—War has introduced a host of new chemicals of unknown toxicity and has accelerated the use of older substances known to be hazardous. Modern industry rests on a chemical base and is constantly creating new problems in industrial hygiene. You will recognize the truth in these observations of the joint authors of this paper, if you read it.

TABERSHAW, I. R., and BOWDITCH, M. Industrial Hygiene. New Eng. J. of Med. 229, 27:1003 (Dec. 30), 1943.

ASSOCIATION NEWS

SECOND WARTIME PUBLIC HEALTH CONFERENCE AND SEVENTY-THIRD ANNUAL BUSINESS MEETING

AMERICAN PUBLIC HEALTH ASSOCIATION

New York, N. Y., October 3-5, 1944

Headquarters: Hotel Pennsylvania

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

John W. Buckley, M.D., Orange Health Unit,
Orange, Texas, Asst. Director, Jefferson-
Orange County Health Units
Emilio Budnik-B., M.D., 615 N. Wolfe St.,
Baltimore 5, Md., Asst. General Inspector,
Chilean Public Health Service
Jose Cobian-Alvarez, M.D., Ysabela 5,
Guayanilla, Mayaguez, Puerto Rico, Health
Officer
Capt. Angelo A. DiDonna, M.C., 34 Jay St.,
Schenectady, N. Y., Chief, Venereal Disease
Section, Station Hospital, Camp Rucker,
Ala.
Manuel A. Frias, M.D., Bruno St., Guayama,
Guayama, Puerto Rico, Health Officer
A. M. Garcia-Ubarri, M.D., Alianza 6,
Santurce, Puerto Rico, Health Officer
Hector M. Gonzalez, M.D., St. A. Lopez,
Humacao, Puerto Rico, Medical Officer
Barbara Hunt, M.D., Lauderdale County
Health Dept., Meridian, Miss., Asst. Director
Rafael U. Lange, M.D., Barcelona, Mayaguez,
Puerto Rico, Health Officer
Angel M. Marchand, M.D., Monterrey Apt.
1A, Terraza Parque, Santurce, Puerto Rico,
Chief, Bureau of Tuberculosis, Health
Dept.
J. W. O'Neill, M.D., 351 Cherry St., Fremont,
Mich., Director, District Health Dept.
George P. Rapp, York Rd. and Horace Ave.,
Abington, Pa., Health Officer

Homer D. Rose, M.D., Wentzel Bldg., Sonora,
Calif., County Health Officer
Nicolas Sanabria-Fernandez, M.D., 22 Espe-
ranza St., San German, Puerto Rico, Med-
ical Officer, Public Health Unit
Jose M. Santiago, M.D., Betancesst, Vega
Baja, Puerto Rico, Health Officer, Insular
Dept. of Health
Francisco Sein, M.D., Vilella 12, Lares,
Puerto Rico, Chief, Public Health Unit
Armando Silva-Navarro, M.D., Camuy,
Aguadilla, Puerto Rico, Medical Inspector,
Dept. of Health
Beatrice E. Steiner, M.D., 35 Ft. Washington
Ave., New York 32, N. Y., Health Officer-
in-Training, Dept. of Health
Gertrud Weiss, M.D., 175 Pinehurst Ave.,
New York 33, N. Y., Health Officer-in-
Training, Dept. of Health
S. G. Zando, M.D., Cinderella Bldg., Wil-
liamson, W. Va., Mingo County Health
Officer

Laboratory Section

Ruby J. Atkins, 1204 Primrose Terrace,
Selma, Ala., Senior Bacteriologist, State
Health Dept.
Mary H. Baker, 2627 Clyde Ave., Los Angeles
16, Calif., Public Health Laboratory Tech-
nician, Los Angeles County Health Dept.
May E. Barry, 1400 Fell St., San Francisco

17, Calif., Clinical Medical Technologist, Southern Pacific Hospital
 Major Abram S. Benenson, M.C., Carlisle Barracks, Pa., Instructor in Military Sanitation
 Walter V. Benion, Unit 2, 183rd Station Hospital, APO 942, Seattle, Wash., Laboratory Technician
 Melvin F. Burgin, 3041 S. 8th St., Abilene, Tex., Laboratory Director, Abilene-Taylor County Health Unit
 Vincent J. DelGiudice, 183rd Station Hospital, APO 942, Seattle, Wash., Laboratory Technician
 Lt. Thaddeus J. Domanski, Sn.C., 225 E. 79th St., New York, N. Y.
 Robert E. Evans, M.S., 939 Margate Terrace, Chicago 40, Ill., Director, Div. of Laboratories, Evanston Health Dept.
 Capt. Hugh F. Fitzpatrick, Sn.C., 141st General Hospital, Memphis 15, Tenn., Chief of Laboratory Service
 Manuel M. Guillermet, P. O. Box 3803, Santurce, Puerto Rico, Supt., Guaynabo Filtration Plant
 Paul W. Jones, 183rd Station Hospital, APO 942, Seattle, Wash., Laboratory Technician
 Capt. Arthur C. Jordan, Sn.C., Station Hospital, Amarillo Air Field, Amarillo, Tex., Asst. Chief, Laboratory Services
 Lucile W. Kircher, Greenwich Hospital, Greenwich, Conn., Senior Technician
 John W. Martello, 183rd Station Hospital, APO 942, Seattle, Wash., Laboratory Technician
 Dr. Alfred N. Metcalfe, P. O. Box 403, Harrisburg, Pa., Chief, Pa. Bureau of Animal Industry Lab.
 Miguel Alonzo Molina, M.D., Calle Arce 41, San Salvador, El Salvador, C. A., Chief, Central Laboratory, Rosales Hospital
 Constance O. Odden, M.S., 310 Builders Exchange, Duluth, Minn., Bacteriologist-in-charge, State Dept. of Health
 Martha G. Papadakis, 1118 Chanslor Ave., Richmond, Calif., City Bacteriologist
 Elizabeth E. Pelkus, 113 Steamboat Rd., Great Neck, N. Y., Bacteriologist, Long Island College of Medicine
 John L. Perhab, P. O. Box 390, Beverly Hills, Calif., Supt. and Mgr., Water Dept., City of Beverly Hills
 Edith Scorup, M.S., 136 State Capitol, Salt Lake City, Utah, Junior Serologist and Bacteriologist, State Board of Health
 Kathleen E. Shanahan, 6415 3rd St., N.W., Washington 12, D. C., Serologist, Arlington County Laboratory
 Capt. Henry A. Stiff, Jr., Sn.C., Station Hospital, Camp Howze, Tex., Asst. Camp Medical Inspector and Hospital Inspector

Raymond D. Tice, M.D., Cor. 3rd and Juniper Sts., Quakertown, Pa., Chief, Chest Clinic, Quakertown Hospital
 Virgil S. Troy, M.S., Continental Can Co., Inc., 4645 W. Grand Ave., Chicago, Ill., Chief, Bacteriological Section, Research Dept.
 Helen E. Vance, 2435 S. 5th E., Salt Lake City 5, Utah, Senior Bacteriologist and Serologist, Div. of Labs., State Board of Health
 Charles L. Walker, M.A., 183rd Station Hospital, APO 942, Seattle, Wash., Laboratory Technician
 Virginia R. Wilson, Station Hospital, Camp Swift, Tex., Bacteriologist
 Jean C. Youngberg, 1522 Ensley Ave., Los Angeles 24, Calif., Bacteriologist, Los Angeles County Health Dept.

Vital Statistics Section

A. Joan Klebba, 1200 16th St., N.W., Washington, D. C., Biostatistician, Office of the Coördinator of Inter-American Affairs
 Deward E. Waggoner, M.S.P.H., 816 Oregon Bldg., Portland, Ore., Director, Div. of Vital Statistics, State Board of Health

Engineering Section

Jose A. Abdelnoor, Agueduct of Ponce, Puerto Rico, Chemist and Director, Ponce Water Works
 Thomas J. Blair, 179 Summers St., Charleston 1, W. Va., General Manager, West Virginia Water Service Co.
 Jose del Carmen-Echevers, 1015 E. Catherine St., Ann Arbor, Mich., Asst. Sanitary Engineer, Panama Government
 Reinerio Castellon-Flores, Suau St., Santurce, Puerto Rico, Electrical Engineer, Dept. of Health
 Isidoro A. Chapa, Jr., Station Hospital, Medical Inspector's Office, Camp Hood, Tex., Senior Sanitary Technician
 Howard W. Chapman, 33 Lee Drive, Lake Forest, Wilmington, N. C., P. A. Sanitary Engineer (R), U. S. Public Health Service
 Elroy K. Day, 420 Sixth Ave., N., Nashville 3, Tenn., Asst. Sanitary Engineer (R), U. S. Public Health Service
 Robert P. Farrell, M.S., 420 Sixth Ave., N., Nashville 3, Tenn., Director, Div. of Sanitary Engineering, State Dept. of Public Health
 Nestor Figarella-Orsini, 70 Palmer, Mayaguez, Puerto Rico, Trainee in Public Health, School of Tropical Medicine
 Franklin Fiske, M.S.P.H., Hartford Board of Health, 550 Main St., Hartford, Conn., Asst. Sanitarian (R), U. S. Public Health Service

Jorge Garcia-Gomez, 808 E. Ann., Ann Arbor, Mich., Student, University of Michigan
 Ernesto Gonzalez-Casillas, Principal St., Anasco, Puerto Rico, Trainee in Public Health, School of Tropical Medicine
 Patrick L. Hughes, 727 Chiles St., Lakeland, Fla., Senior Sanitarian, Polk County Health Dept.

K. A. Keirn, 171 Second St., San Francisco 5, Calif., Division Manager, Wallace & Tierman Sales Corp.

Bernard J. Langdon, Box 47, Olathe, Kansas, Asst. Engineering Sanitarian, U. S. Public Health Service

James I. Maston, General Delivery, Richland, Wash., General Sanitarian, Hanford Engineer Works

Rafael Miranda-Franco, 8 Colon St., Stop 43½, P. O. Box 7048, Santurce 29, Puerto Rico, Asst. Public Health Engineer, U. S. Public Health Service

Luis D. Palacios, Ponce de Leon 177, Santurce, Puerto Rico, Sanitary Engineer and Chief, Bureau of Malaria Control, Health Dept.

Fernando C. Ramirez, C.E., Box 565, Guayama, Puerto Rico, District Sanitary Engineer, Dept. of Health

Carlos Raul-Saavedra, Allen 71, San Juan, Puerto Rico, Trainee in Public Health, School of Tropical Medicine

Carlos Rivera-Gonzalez, Villaverde No. 13A-Hos, Santurce, Puerto Rico, Student, School of Tropical Medicine

Henry Rodriguez-Fernandez, 32 Hipodromo St., Santurce, Puerto Rico, Student, School of Tropical Medicine

James H. Simmons, 15 Linden St., Weston, W. Va., Sanitarian, State Dept. of Health

Albert H. Stevenson, Hamilton-Glenwood Gardens, Yonkers, N. Y., Asst. Sanitary Engineer, U. S. Public Health Service

Wilfred Taylor, 581 Rosedale Ave., Winnipeg, Man., Canada, Inspector, Div. of Sanitation, City Health Dept.

Manuel A. Torres-Aguilar, Urb. Stadium, Caguas, Puerto Rico, Student, School of Tropical Medicine

Industrial Hygiene Section

Ida B. Banfield, Nellis, W. Va., Nurse

Hazel D. Jamison, R.N., Kopperston, W. Va., Visiting Nurse, Koppers Coal Div.

Lt. Col. Henry N. Parrish, Sn.C., Hdq.A.S.C., Patterson Field, Fairfield, Ohio, Chief, Industrial Hygiene Engineering, A.A.F., Air Service Command

Americo Rodriguez-Nazario, Boulevard Santiago Veve, Mayaguez, Puerto Rico

Food and Nutrition Section

Teresa Anglero-Diaz, San Lorenzo, Puerto Rico

Dorothy DeHart, M.A., Roosevelt Hospital, 428 W. 59th St., New York 19, N. Y., Chief Dietitian

Marion E. French, 605 W. 112th St., New York 25, N. Y., Nutritionist, City Dept. of Health

Mathew Klein, M.S., 18 Shephard Ave., Newark, N. J., Owner, Garden State Dairy Lab.

Mildred Krohn, 703 State Bldg., Los Angeles 12, Calif., District Nutritionist, State Dept. of Public Health

Loucille G. Langham, M.S., 1901 Hopi Trail, Austin, Tex., Nutrition Consultant, State Dept. of Health

Gertrude G. Mudge, A.M., 404 Riverside Drive, New York 25, N. Y., Supervising Nutritionist, Dept. of Health

Ernest S. Tierkel, V.M.D., 328 W. 89th St., New York, N. Y., Veterinarian, Meat Inspection Div., W.F.A.

Walter Wilkins, M.D., 1800 14th St., N., Arlington, Va., Public Health Nutrition Consultant, U. S. Public Health Service

Maternal and Child Health Section

Lily G. Harris, D.O., 461 Bellevue Ave., Oakland, Calif., Director, East Bay Osteopathic Clinic

Keith O. Taylor, 5105 Dover St., Oakland 9, Calif., Administrator, Children's Hospital

Public Health Education Section

Florence M. Albrecht, 1101 Martin Place, Ann Arbor, Mich., Student, Univ. of Michigan

Mary C. Baker, 33 River St., Boston, Mass., Health Education Worker, Div. of Child Hygiene, State Health Dept.

Wilma Becknell, 228 S. Thayer St., Ann Arbor, Mich., Student, Univ. of Michigan

Olaf Haraldson, M.D., Minot, N. D. Elected Member 1942, Health Officers Section

William M. Randolph, M.D., Charlottesville, Va. Elected Member 1936, Public Health Education Section

William V. Sanford, M.D., (Major M.C.), Ripley, Tenn. Elected Member 1930, Health Officers Section

Armin V. St. George, M.D., New York, N. Y. Elected Member 1934, Laboratory Section

DR. HALVERSON APPOINTED CHAIRMAN
OF THE COMMITTEE ON ADMINISTRATIVE PRACTICE

The Executive Board has announced the appointment of Dr. Wilton L. Halverson, State Director of Public Health in California, as Chairman of the Committee on Administrative Practice. He succeeds Dr. Henry F. Vaughan, resigned.

Dr. Halverson is a graduate in medicine from the College of Medical Evangelists in 1929. For some years he has been Professor of Public Health and Preventive Medicine in his alma mater. In 1932 he received a doctorate in public health from Yale University. Dr. Halverson served as District Health Officer in the Los Angeles County Health Department for four years and as Health Officer of Pasadena from 1934 to 1942, when he became Health Officer of Los Angeles County. He was appointed to his present post as State Director of Public Health in 1943 by Governor Warren. Dr. Halverson has served as Vice-President of the American Public Health Association and has been active in the affairs of the Western

Branch. He is a Fellow of the Health Officers Section. One of his first official acts as State Director of Public Health was to authorize a survey of the department's organization and activities, which was completed under the auspices of the Committee on Administrative Practice in 1943. Dr. Halverson has recently been appointed a member of the Board of Scientific Directors of the Rockefeller Foundation.

A.P.H.A. MERIT SYSTEM UNIT SERVES
SIXTEEN STATES

The Association's Merit System has announced that more than 70 examinations have now been prepared in response to requests from merit system and civil service agencies in 16 states. Questions for public health nursing examinations have been most in demand. Other examinations available include health officers, sanitarians, and laboratory workers in various grades. The public health engineering field will shortly be covered, and examinations for various medical specialists in public health will be undertaken by the staff of the Unit.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

Wanted: A physician trained in tuberculosis to assume administrative control of the Bureau of Tuberculosis in an eastern city of 200,000 population. Salary \$4,500-\$5,031 plus cost of living adjustment. Address Box B, Employment Service, A.P.H.A.

Sanitarian wanted: Preferably with Bachelor's degree or engineering degree, plus public health experience or training. Must have own car. Applicant with lower qualifications will be offered an opportunity to take a short, free indoctrination course. Salary \$1,920 per year with travel allowance of \$50 per month, if qualified. Apply Dist. Dept. of Health, No. 6, Central Office, Newberry, Mich., Dr. Franklin.

Wanted: Pediatrician to supervise medical care of children at cerebral palsy center being established by private institution in cooperation with Illinois Division of Services for Crippled Children. Salary commensurate with experience and training. For further information write Lawrence J. Linck, Director, Division of Services for Crippled Children, 1105 So. Sixth St., Springfield, Ill.

The Department of Health, New Jersey, whose industrial health activities have expanded rapidly during the present war, has announced its need for two full-time industrial hygiene physicians for its Industrial Hygiene Service. As one of the leading states in the production of war materials, New Jersey offers unusual opportunities for gaining experience in occupational disease control besides giving the physician a chance to make a valuable contribution to the war effort. The principal duties of the selected physicians will be consultations in regard to the following: control of occupational diseases; industrial toxicological problems; evaluation of adequacy of plant medical services; promotion of measures which will reduce absenteeism from non-occupational causes; and conduct of industrial health education activities. Physicians interested in these positions should

write to the Department of Health, Trenton, N. J.

The Milwaukee Health Department is interested in obtaining an instructor in hospital nursing to conduct a student educational program in its communicable disease hospital. Salary offered begins at \$125 per month with maintenance, and increases of \$5 per month each year until \$135 has been reached. To this basic salary there has been added a cost of living bonus of \$30.64 per month, making the total beginning salary \$155.64 plus maintenance. Apply to Dr. G. F. Burgardt, Deputy Commissioner of Health, Milwaukee, Wis.

Wanted: Public health physicians in Texas. George W. Cox, M.D., State Health Officer, Austin, Tex.

Hawaiian Territorial Board of Health seeks trained engineer to supervise rodent plague control program. Salary range from \$331.67 to \$398.33 per month subject to retirement deductions plus bonus. Position under Territorial civil service system with classification of P-4. For further details address A.P.H.A. Employment Service.

Wanted: Physical therapist by Crippled Children's Division. Should be graduate of a school of nursing or of college, with a major in physical education or science; have completed a course in physical therapy; should have had experience in physical therapy, preferably with children. Write for application blank to Merit System Council, 416 Henry Building, 309 S.W. 4th Ave., Portland 4, Ore.

Psychiatric case worker desired for mental hygiene clinic, Department of Health, Peoria, Ill.

Senior Sanitarian, Alaska Health Department. Minimum requirements 2 years college, 6 months public health course, 2 years' experience. Two additional years' experience acceptable instead of each year college. Monthly salary \$235-

\$265. Mary B. Pool, Alaska Merit System, Juneau.

Michigan announces civil service positions now open for orthopedic public health nurse, Grades II and III classes with the Michigan Crippled Children's Commission. Salary range: Grade II \$230 to \$270 per month; Grade III \$280 to \$340 per month. Grade II not under 23, Grade III not under 25. Must have completed course in orthopedic nursing or physical therapy in approved school. For Grade III position a full-time course of at least 9 months' duration is required. Must have 3 years' experience in public health nursing, one year of which shall have been in supervisory capacity. For Grade III position one additional year of nursing and one additional year of supervisory experience required. Eligibility for certificate in public health nursing and registration as a nurse in Michigan. For further information write Michigan Civil Service Commission, 310 No. Grand Ave., Lansing 4, Mich.

Wanted: Sanitary engineer or chemist to assist in stream pollution survey and later in study of sewage treatment. Should be qualified to perform chemical and bacteriological analyses of water and sewage and chemical analyses of industrial wastes. Nine months employment with possibility of indefinite continuation, particularly if person is willing to do some other types of analytical work, including coal analysis. Salary \$175-\$250 per month depending on qualifications. Women considered. Address communications to Prof. Gilbert H. Dunstan, Dept. of Sanitary and Public Health Engineering, University of Alabama, Box 1996, University, Ala.

Industrial Hygiene Toxicologist. Calls for person of chemical or chemical engineering background. Position, supervising of chemical work of industrial hygiene service and industrial hygiene laboratory; designing special apparatus for field studies on occupational disease problems; conducting field and laboratory analyses of toxicological exposures in industry; keeping records, interpreting results and preparing records. Requirements, knowledge of chemical laboratory methods and equipment; procedures for qualitative and quantitative analysis of organic and inorganic chemistry; knowledge of chemical methods of determining toxic materials in industry; familiarity with petrographic methods of mineralogical analysis. Immediate temporary appointment will be made, to be followed later by civil service examination to determine permanent status. Salary \$2,900 base, plus \$100 a year war adjustment,

or total of \$3,000 per year. Travel expenses also allowed. Must be U. S. citizen. Resident of any state may apply. Write J. Lynn Mahaffey, M.D., Director of Health, State Department of Health, Trenton 7, N. J.

Wanted: Public Health Nurse. Salary \$175 per month and full maintenance, plus \$25 per month for car expense. Must furnish own car. Write Paul D. Crimm, M.D., Director Boehne Tuberculosis Hospital, Evansville 12, Ind.

City of 70,000, southeastern U. S., seeks qualified health commissioner between the ages of 30 and 45, draft exempt. Salary \$4,500 plus auto allowance of \$300 per year. Box V, Employment Service, A.P.H.A.

Assistant Sanitarian in well established Ohio department of health. Minimum experience 2 years required. Merit system prevails. Salary \$1,800-\$2,400. Write Box K, Employment Service, A.P.H.A.

Wanted: Bacteriologist to conduct virus laboratory in the Laboratory Section of the Health Division, City of St. Louis. Applicant must have graduate degree with research and practical experience in virology. Salary range from \$220 to \$360 a month, depending upon ability. Position under Civil Service. Write Box W, Employment Service, A.P.H.A.

Wanted: Statistical clerk, preferably with college degree and experience in health education, to study and analyze vital statistics in suburban and rural county adjacent to Washington. Special emphasis on relation to health department services and participation in Health Honor Roll. Address V. L. Ellicott, M.D., Dr.P.H., Montgomery Co., Rockville, Md.

Wanted: Medical Social Worker for Dept. of Health, Peoria, Ill. Address Director Maternal and Child Health, Dept. of Health, Peoria, Ill.

Wanted: Physician in eastern city of 200,000 population as Director of Bureau of Maternal and Child Hygiene. Salary \$4,500-\$5,031, plus cost of living adjustment. Address Box C, Employment Service, A.P.H.A.

Wanted: Physician (male), American citizen, draft exempt, trained in pediatrics, for a 3 year position as chief resident and research assistant in fine pediatric tuberculosis hospital, New York. Good salary and maintenance. Only one intensely interested in research need apply. Send full details of qualifications and photo-

graph. Box R, Employment Service, A.P.H.A.

Wanted: X-ray technician to travel with portable x-ray unit taking chest x-rays at tuberculosis case finding clinics. Includes both industrial and school surveys. Salary \$35 per week plus travel and maintenance when away from headquarters. Address Box M, Employment Service, A.P.H.A.

Wanted: Resident physician for plant in South America. Must have thorough knowledge of malaria, tropical medicine, and vector control. Must be eligible for licensure in British Colony. Address Box H, Employment Service, A.P.H.A.

Physician wanted as Director of Maternal and Child Health in western county health department. Preferably with training in pediatrics and venereology. Some venereal disease control work also. Man preferred but woman considered. Must be in good health. Salary \$4,500 per year with car and expenses furnished. Position for duration of war. Address Box S, Employment Service, A.P.H.A.

Tuberculosis Association in large western city seeks a trained and experienced health education director, a director of medical social work, and a public health nurse supervisor. Attractive positions now open in agency with a dynamic program closely related to official groups. Address Box D, Employment Service, A.P.H.A.

U. S. Indian Service seeks physicians for service in the United States and Alaska. Address Office of Indian Affairs, Health Division, Merchandise Mart, Chicago 54, Ill. Application blanks will be furnished upon request.

Wanted: Medical technologists, also bacteriologist for 550 bed approved California hospital. Give full particulars and state salary desired. Address W. O. Brown, M.D., Kern General Hospital, Bakersfield, Calif.

Wanted: Medical technologist, woman, trained in bacteriology of milk and water, diagnostic cultures, routine blood chemistry and tissue work—paraffin and frozen sections. County position under Civil Service located in the East. Salary to be arranged. Write Box L, Employment Service, A.P.H.A.

Wanted: M.D., instructor in preventive medicine and public health, with interest particularly in biostatistics and industrial hygiene. Salary approximately \$4,000. Write Box T, Employment Service, A.P.H.A.

Wanted: Competent, thoroughly trained bacteriologist, woman or draft exempt man, to take complete charge of splendidly equipped small industrial laboratory, Connecticut location, country environment, pleasant surroundings, excellent working and living conditions. This is a permanent post-war position. Write full details including minimum salary requirement to start in first letter. All letters including adequate vitae and photo will be promptly acknowledged. Write Box A, Employment Service, A.P.H.A.

St. Louis, Mo., Health Division, Industrial Hygiene Service, seeks two industrial hygienists, either engineers or chemists. Salaries \$225 to \$250 per month depending on qualifications and experience, plus travel allowances. Address Robert M. Brown, Public Health Engineer, 64 Municipal Courts Bldg., St. Louis 3, Mo.

Woman with background of health education and public health nursing, experienced as teacher, supervisor, and writer, seeks teaching position of responsibility. H-507

Health educator with Master's degree in public health and some experience. Prefers position in official agency. H-510

LABORATORY

Research bacteriologist. Unusually trained and experienced woman bacteriologist and serologist now occupying responsible position in state laboratory

seeks research work of permanent character. L-468

Water chemist, bacteriologist, M.S. degree in Sanitary Chemistry. Age 36, draft exempt. Eight years' experience in state laboratory working on water, milk and sewage. Prefers Midwest or Pacific Northwest location. L-469

ENGINEER

Well qualified public health engineer seeks responsible position in New York metropolitan area. E-480

MISCELLANEOUS

Public Health Nurse. B.S. in nursing, William and Mary College, age 53, seeks position as coördinator of public health nursing, educational director, or director student nurse public health program. Prefers Middle Atlantic States. M-452

NEWS FROM THE FIELD

OCD CHANGES CHIEF MEDICAL OFFICERS

The Office of Civilian Defense in Washington has announced that George Baehr, M.D., Medical Director (R) U.S.P.H.S., retired on March 1 after 2½ years of service as Chief Medical Officer of the OCD. He will be succeeded by W. Palmer Dearing, M.D., U.S.P.H.S., who has been assistant chief medical officer since the establishment of the Medical Division of the OCD.

Dr. Baehr, in 1941, resigned a reserve commission in the Army to accept a commission as Medical Director in the U. S. Public Health Service for assignment to the newly created Office of Civilian Defense to organize its medical division. Under his direction a staff of technical experts was assembled, regional medical and sanitary engineering offices were established, and an emergency medical service was organized in each state and local community throughout the country. An organization for protection against war gases was set up in the coastal states and in the major industrial centers in the interior. A program of protection and mutual aid for water supply systems and sanitation facilities was established in all states.

According to the OCD, the Medical Division has established a nation-wide system of casualty receiving hospitals, 321 potential emergency base hospitals in 20 coastal states, 180 hospital blood and plasma banks, reserve depots of dried and frozen plasma in 400 cities, more than 120 affiliated hospital units, and 80 emergency nursing units. In recognition of Dr. Baehr's services to the hospitals of the country in time of war, the American Hospital Association at its recent annual meeting voted a

special citation to Dr. Baehr and elected him to honorary membership.

NEW OFFICERS OF PENNSYLVANIA PUBLIC HEALTH ASSOCIATION

At a meeting on January 25, the Pennsylvania Public Health Association elected the following officers:

Honorary President—A. H. Stewart, M.D., Harrisburg

President—Henry J. Benz, M.D., Pittsburgh
President-Elect—Harriet L. Hartley, M.D., Philadelphia

Vice-President—Richard P. Lienhardt, V.M.D., Wayne

Secretary-Treasurer—C. E. Houston, Washington

Representative to A.P.H.A. Governing Council—W. W. McFarland, M.D., Pittsburgh

U. S. PUBLIC HEALTH SERVICE AID IN THE RELOCATION OF PHYSICIANS AND DENTISTS

The following is an official statement published at the request of the U. S. Public Health Service:

During its last session, Congress passed a deficiency appropriation bill which included an authorization to the U. S. Public Health Service to enter into agreements with and make certain payments to physicians and dentists to relocate in communities needing medical and dental services. On December 23, 1943, this measure became Public Law 216, 78th Congress.

The law is designed to provide relief to those areas which for various reasons have undergone the hardship of inadequate medical and dental care. Many of these communities have lost their doctors and dentists to the armed forces.

The law also provides an opportunity for the physician or dentist who has wanted to set up practice in another community, but has hesitated because of the financial risk of those first months

during which he and the families in the new town are becoming acquainted. Now, with a 3 month allowance assured and with transportation paid for him, he can make that move with less fear of financial loss.

Any municipality, county, or other local subdivision of government may file an application to secure a physician or dentist. Application forms are secured from the state health department. The application is executed by the legally authorized representative of the community (the city manager, mayor, chairman of the county board of supervisors, county judge, etc.). The application is sent, with the community's remittance of \$300, made payable to the Treasurer of the United States, to the state health department for approval. When this approval is given, the state health department forwards the community's application and \$300 to the U. S. Public Health Service.

Upon the receipt of the community's application and payment of \$300, the Public Health Service can enter into an agreement with a physician or dentist who has a permit to practise in the state in which the applicant community is located, who agrees to practise in that community for at least one year, and who is acceptable to the community. The costs of transportation of the physician or dentist, his family and household effects, are paid. In addition, a monthly allowance of \$250 a month for 3 months will be paid to the doctor. Of the total cost of transportation and relocation allowance, 75 per cent is contributed by the U. S. Public Health Service; 25 per cent by the community to which the doctor is relocated.

The total relocation cost to the community will be about \$300. If the community's obligation should exceed \$300, the balance due must be remitted to the U. S. Public Health Service upon the latter's request. If it is less

than \$300, the excess will be refunded to the community.

After a written agreement between an individual physician or dentist and the U. S. Public Health Service has been concluded, the first monthly relocation allowance to the physician or dentist accrues from the date of the latter's arrival at the new location. The second and third payments are made at the end of the second and third months.

Travel and transportation costs can be paid in either of two ways. The physician or dentist who has a written agreement with the Public Health Service can apply to the latter for Government transportation requests, and Government bills of lading. If this arrangement is carried out, the Government is billed and the physician or dentist does not have to use his own funds to cover this expense. Or, if he prefers, he may pay travel and transportation himself and be reimbursed for actual and necessary expense upon presentation of his claim to the Public Health Service. These claims must be supported by receipts in so far as possible.

The physician or dentist relocating under agreement with the Public Health Service remains a private, self-employed professional individual. His relation to the community is the same as that of any other private doctor except that he must practise in the new location at least one year. The Public Health Service simply assists in getting together the community that needs a physician or dentist with the professional man who has the necessary permit to practise and who agrees to serve that community in his professional capacity.

The purpose of this relocation plan is to mitigate the doctor shortage, which in some places has been created, in others intensified, by military absorption of medical and dental personnel. The success of the plan will depend in large measure upon the response of

the individual doctor, the initiative of the needy community, and, above all, upon the extent to which the wishes of the applicant communities coincide with the preference of the doctors who volunteer to serve under this plan.

HOSPITAL MEN VOLUNTEERS

The U. S. Office of Civilian Defense in coöperation with the American Hospital Association has published a bulletin for hospital administrators with suggestions for solving serious manpower shortage problems and the cultivation of hospital men volunteers. This OCD publication 5013 should be used with OCD publication 3632, A Guide for Local Defense Councils for training volunteers for war services. Requests for copies should be addressed to the U. S. Office of Civilian Defense, Washington.

DELAMAR INSTITUTE, NEW YORK, TO EXPAND TROPICAL MEDICINE

Dr. Harry S. Mustard, the Director of the DeLamar Institute of Public Health, Columbia University, New York, recently announced plans to establish a center in tropical medicine involving new building facilities and expanded personnel with additional laboratories and equipment.

With hundreds of thousands of troops in tropical areas who are threatened by infections and epidemics, an acute need has developed for personnel trained in methods for fighting tropical diseases. Dr. Mustard said: "Alliances, treaties, national policies and trade interests are more than ever carrying Government officials, business men, advisers, physicians and technicians into places whose names they could not have pronounced before the war. They go and will continue to go by ships and airplanes to the uttermost corners of the earth."

According to Dr. Mustard, a substantial temporary grant has been received from the Josiah Macy, Jr.,

Foundation which will be used in the study of tropical medicine under the new program. A further grant has been received from the John and Mary Markle Foundation for research in filariasis, and provisions have been made for increased instruction in tropical medicine for undergraduate medical students.

REORGANIZATION OF U. S. PUBLIC HEALTH SERVICE STAFF

Surgeon General Thomas Parran of the U. S. Public Health Service recently announced the following appointments authorized under legislation affecting the Service:

Assistant Surgeon General Lewis R. Thompson, in charge of the Bureau of State Services

Assistant Surgeon General Rolla E. Dyer, director of the National Institute of Health

Assistant Surgeon General Ralph C. Williams, in charge of the Bureau of Medical Services

Assistant Surgeon General (Dental) William T. Wright, Jr., chief of the Dental Division

Assistant Surgeon General (Sanitary Engineering) John K. Hoskins, chief of the sanitary engineering division

Medical Director Paul M. Stewart, chief, Division of Commissioned Officers

Medical Director Lawrence Kolb, chief, Mental Hygiene Division

Medical Director Joseph W. Mountin, chief, States Relations Division

Medical Director William F. Ossenfort, chief, Hospital Division

Medical Director Gilbert L. Dunnahoo, chief, Foreign Quarantine Division

HERMANN M. BIGGS MEMORIAL LECTURE

The Hermann M. Biggs Memorial Lecture, held annually in Hosack Hall, New York Academy of Medicine, under the auspices of the Committee on Public Health Relations, will be delivered this year on Thursday, April 6, at 8:30 P.M., by Wilbur A. Sawyer, M.D., Director of the International Health Division of the Rockefeller Foundation. The subject of the lecture will be "International Health." This lecture is open to the general public.

NORTH DAKOTA WORKERS ATTEND
SCHOOL ADMINISTRATORS
INSTITUTE

The North Dakota State Department of Health, Bismarck, has announced that 30 North Dakota school administrators from the University, teachers colleges, junior and senior high schools, as well as 3 members of the staff of the State Department of Public Instruction, attended an Institute in Health Education for school administrators held at the Center for Continuation Study, University of Minnesota, recently. The arrangements for the Institute were under the direction of Ruth E. Grout, Ph.D., of the College of Education and the Department of Preventive Medicine and Public Health of the University of Minnesota.

DR. RECIO APPOINTED CUBAN MINISTER
OF HEALTH

President Fulgencio Batista on March 6 announced the appointment of Dr. Alberto Recio Forns, as Minister of Health to replace Dr. Juane Portuondo Domenech, resigned. Dr. Recio for several years has been technical chief of medical services in the Ministry of Health and is well known to his North American colleagues from his attendance at annual meetings of the Association.

PROGRESS IN STUDENT NURSE
RECRUITMENT

A coöperative campaign by nurses, hospital administrators, educators and civic leaders to meet the year's quota of 65,000 new student nurses was mapped out at a meeting on February 24 of the recently reorganized Committee on Recruitment of Student Nurses, called by the National Nursing Council for War Service.

Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, in a message read by Lucille Petry, a member of the committee, called for "the

largest fall classes in the history of most schools of nursing, if known national war needs are to be met."

Pointing out that the 65,000 quota was an absolute minimum based on the number of students who could be admitted to schools, Miss Petry stated that in order to reach that goal, 23,000 students would have to be enrolled between January 1 and May 30, and another 5,000 in June classes. Summer and fall admissions in 1943, she said, had reached a total of 41,270. The shortages hampering more rapid expansion of schools of nursing, namely, shortage of clinical facilities, of well qualified instructors, and of housing facilities, were not insurmountable, in her opinion, and steps were being taken to overcome them as soon as possible.

More than 1,100 schools of nursing have applied for admission to the U. S. Cadet Nurse Corps program and approximately 1,000 units have already been approved. These are distributed fairly evenly throughout the country. U. S. Cadet Nurses now number 92,000 enrolled in all classes in schools of nursing, about half of these being new enrollees.

CALIFORNIA OFFERS COURSE FOR
SANITARIANS

The School of Public Health, University of California, Berkeley, has announced that 25 sanitarians are currently in attendance at the special training course for sanitarians which began on March 3 and will run through the month of May. The course will include public health administration and organization, communicable diseases and their control, general epidemiology and public health statistics, together with sanitary science and sanitary inspection. Arrangements for the course are under the direction of Dr. Walter H. Brown, the Acting Dean. W. S. Mangold is supervising the instruction.

WILLIAM J. ORCHARD HONORED

William J. Orchard, General Manager of Wallace & Tiernan, Inc., was designated as the "Outstanding Citizen for the year 1943" in a citation from the Chamber of Commerce and Civics of the Oranges and Maplewood, New Jersey, presented at the annual dinner of the Chamber on February 15.

This citation supplemented the one given him on December 7, 1943, by the Belleville Manufacturers Association, Inc., of Belleville, N. J., in which city the Wallace & Tiernan plant is located. The Belleville citation, the first one awarded by the Association, was given on the occasion of its twelfth anniversary, and states that Mr. Orchard's "services to management and labor in our communities in World War II have been of paramount importance to the economic, industrial, and civic life of this area."

Mr. Orchard is General Chairman of the Community Manpower Mobilization Committee, a committee of businessmen and industrialists which he formed in order to solve the labor needs of the Newark Area of the War Manpower Commission. It is reported that the results have earned praise from high government officials, that war production in the area has increased, labor turnover has decreased, and thousands of new people have gone to work in war industry.

INDUSTRIAL HYGIENE CONFERENCE

The Second War Conference of industrial physicians, industrial hygienists and industrial nurses will be held in St. Louis, Mo., May 8-14, at the Hotel Jefferson. The participating organizations are: American Association of Industrial Physicians and Surgeons, American Industrial Hygiene Association, National Conference of Governmental Industrial Hygienists, and American Association of Industrial Nurses.

PERSONALS

Central States

FLOYD C. BEELMAN, M.D.,† with the Assistance of HARRY R. ROSS, M.D.,† Topeka, Kan., is directing the work of the Division of Maternal and Child Health of Kansas State Board of Health, pending the appointment of a person to succeed William Fred Mayes, M.D., resigned. Dr. Beelman is Secretary of the State Board.

ALBERT FISHER, M.D., North Judson, Ind., has been appointed Health Officer of Starke County, succeeding Dr. WILLIAM J. SOLT, San Pierre.

ESTHER FRENDBERG, Nutritionist for the North Dakota State Department of Health since June 1, 1943, has been appointed Executive Secretary of the State Nutrition Council of the North Dakota Defense Council. Miss Frendberg has been granted a leave of absence to accept this post. She has been a home economics instructor in Mohall and Mandan High Schools in North Dakota since graduating from the North Dakota Agricultural College.

DOUGLAS H. FRYER, M.D., D.P.H.,† formerly Director of the Bay County Health Department, has been appointed Field Medical Director and Assistant Director of the Bureau of Local Health Services of the Michigan Department of Health, Lansing.

CLARENCE A. HARTLEY, SR., M.D., has been appointed Health Officer of Evansville and Vanderburgh County, Ind.

WILLIAM H. HEADLEE, PH.D., recently appointed Head of the Division of Tropical Medicine and Parasitology at Indiana University School of Medicine, Indianapolis, Ind., left in March to conduct a study of tropical

* Fellow A.P.H.A.

† Member A.P.H.A.

diseases in Guatemala, Honduras and Costa Rica. Dr. Headlee was chosen for the work by the Association of American Medical Colleges, the study to be financed by the Markle Foundation in coöperation with the Army Medical Corps.

OSCAR S. HELLER, M.D., Greenfield, Ind., has resigned as Health Officer of Hancock County, Ind.

WALLACE D. HUNT, M.D.,† of the Reserve staff, U. S. Public Health Service, has been assigned to the Division of Public Health, Minneapolis, Minn., to assist F. E. HARRINGTON, M.D.,‡ the Commissioner of Health.

DAVID LITTLEJOHN, M.D.,* Saulte Ste. Marie, Mich., for the past 7 years Director of the Chippewa County Health Department, became Director of the Wayne County Health Department.

LEWIS A. MOORE, M.D., has been appointed Health Officer of Monroe, Wis.

WILLIAM SAMBORSKI † of the Detroit Department of Health has been appointed to conduct a cross-connection survey for the City of Ann Arbor, Mich. This survey is sponsored jointly by the Water Department and the Department of Public Works.

R. M. SORENSEN, M.D.,* who is in charge of the Division of Venereal Disease Control in the Kansas State Board of Health, Topeka, has been appointed acting secretary of the Kansas Public Health Association in the place of FRED MAYES, M.D.,‡ resigned, who has joined the staff of the U. S. Children's Bureau, Washington.

WILLARD C. SUMNER, M.D., has been appointed Health Officer of Edgerton, Wis.

Eastern States

JAMES D. LEWIS, M.D., of Scranton, Pa., has been appointed Health Director of Lackawanna County, succeeding WILLIAM T. DAVIS, M.D.

WILLIAM G. MORGAN, M.D.,† has been appointed Director of the Clark County Health Department, Winchester, Ky.

FRANK M. STEAD,* Associate Professor of Sanitation at the School of Medicine at Galveston, University of Texas, according to *Science*, has resigned to take charge of studies on industrial hygiene for the California State Board of Health at Berkeley. His successor is JOE B. WINTON, formerly associated with the Harris County Health Department.

JAMES H. WELLS, M.D., Pineville, Ky., has resigned as Health Officer of Belle County, Ky.

EDGAR H. WILLARD, M.D., DR.P.H.,† Berkeley Springs, W. Va., has been appointed as part-time Health Officer for Morgan County.

ROBERT D. WRIGHT, M.D.,† former venereal disease consultant attached to the North Carolina State Board of Health, has been assigned as Medical Officer in charge of the new Kanawha Valley Medical Center at South Charleston, W. Va.

MARTIN D. YOUNG, Sc.D.,† Senior Parasitologist, National Institute of Health, has been commissioned as Sanitarian (R) in the U. S. Public Health Service. Dr. Young is in charge of the Malaria Research Laboratory of the National Institute of Health located at Columbia, S. C., and also of the newly organized "Imported Malaria Studies" program.

Western States

J. L. JONES, M.D., DR.P.H.,* Director of the Division of Industrial Hygiene in the Utah State Department of Health, Salt Lake City, and formerly State Health Commissioner of Utah, has resigned to become Chief of Medical Services of the Washington State Department of Health, Seattle.

LYNN J. LULL, M.D.,* has been appointed Director of Local Public Health Services in Idaho. He was

Preparation of Health Education Personnel for the War and Post-war Periods*

The Responsibility of the School of Public Health

HUGH R. LEAVELL, M.D., DR.P.H., F.A.P.H.A.

*Director of Health, Louisville and Jefferson County Health Department,
Louisville, Ky., and Professor of Public Health, University of Louisville
School of Medicine, Louisville, Ky.*

THE job of training personnel for work in the health education field "is not by any to be entered into unadvisedly or lightly," in the words of the *Book of Common Prayer*.

Seventy years ago Elisha Harris,¹ the first secretary of the American Public Health Association, recognized the importance of health education in his statement, "The permanent value and success of any methods or system of sanitary government will depend upon the degree in which the people are generally enlightened, concerned, and made responsible, in regard to their sanitary duties." As a laconic former president of the United States reputedly said on the birthday of a septuagenarian, "Seventy years is a long time." How-

ever, even after such a long period, in the fairly recent words of Hiscock,² "We must not assume that there is a well articulated 'science' of public health education. The pillars—psychological, sociological, and pedagogical—are themselves none too steady."

A suitable training program for this broad and varied field has been mapped out only with great difficulty. As in many other now well established branches of public health and the social sciences, health education in its early developmental period had to be hewn out more or less from solid rock. And this was done by a relatively small group of geniuses with the innate ability and the broad viewpoint which would have insured success in practically any field of endeavor. The time has now been reached where more or less of a mold may be set up, and a degree of mass production may to a

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

degree replace the relatively slow custom-built method of development.

Five years ago the Subcommittees of the Committee on Professional Education of the A.P.H.A.^{3, 4} prepared two blueprints; one for the education of school health educators, and another for adult health educators. A more recent report of the parent committee⁵ includes both types of workers in a more or less common mold. This indicates the feeling that, though the application may be different, similar educational backgrounds may serve satisfactorily in both types of work. This later report, in addition to outlining certain professional qualifications desirable for health educators, concludes that a number of personal characteristics are also important. Among such traits are: creative ability, leadership, good personal health, good judgment, pleasing personal appearance, common sense, adaptability, ability to work with people, ability to size up and meet situations, and the ability to present pertinent facts simply and effectively. It is evident that the importance of health education is now fully realized if paragons such as this are to be required to do the job.

Seriously, however, the report of this committee which has done so much to improve standards for public health personnel, gives an excellent picture of the job to be done and the types of training required properly to fit an aspirant for the work. As the committee carefully points out, a major portion of this training must be completed before the future health educator enters a school of public health. The basic cultural and science background, or its practical equivalent, must be acquired in college, leaving only the completion of the educational process for the postgraduate school. Obviously one who decides upon this field at the time of entering college is in a position to get better preparation than would

otherwise be the case. A candidate with preparation in psychology, education, economics, sociology, and enough of the basic sciences to acquire a full appreciation of the scientific method makes the job of the public health school relatively simple. With this sort of a beginning it is necessary only to add training in hygiene and public health, public administration, and the special skills required in health education, followed by carefully planned and supervised field experience in some suitable health agency. Probably most of us will agree with the principles outlined in the committee report. From the viewpoint of public health schools certain features of the training program require more complete discussion.

Since the proper college background is so vital, the schools of public health should make suitable contacts with vocational advisers in colleges likely to give preliminary training to future health educators. Such advisers need to become fully acquainted with the health education field and the type of training required so that the subject may be presented to students in the favorable light it merits. Students showing an interest might well be encouraged to get in touch with one or more of the schools of public health fairly early in their college courses so that they may be able to plan their work effectively. There would also be an advantage in giving the person responsible for admission to the public health school an opportunity to size up the candidate so that he can advise whether success in the health education field is likely from the personality standpoint.

Like health departments and most voluntary health agencies, public health schools do not have all the facilities and personnel they would like. This situation has a very bright side, however. It forces the public health school to go out into the surrounding community and into the faculties and laboratories of

other schools of the university with which it is associated for teaching assistance and for learning opportunities. Some public health students in the past have felt the lack of sufficient contacts with agencies actually working in the community. Doubtless no one in the health field has more work with outside agencies than the health educator, and such contacts as can be made during student days will bear rich fruit in later years. Agencies available to the public health school may vary in quality; but there will be some variation in the quality of community agencies everywhere. Medicine progresses through a knowledge of pathology as well as by a study of physiology, and a few pathological agencies thrown in for good measure will make better clinical material. How good would medical students be who had their training from the examination of only normal persons? Unquestionably the intensive period of field work, which will come after the formal training, is of the greatest importance. My argument is for beginning this sort of thing even earlier than during the period of "internship."

Some public health schools have made it an established policy to keep in close touch with their graduates, even to the point of serving as a sort of employment agency for the students, as well as for employers interested in obtaining qualified personnel suited for particular tasks. This policy has many advantages in addition to the obvious one of finding round holes for round pegs and vice versa. If the school keeps in close touch with its alumni, it can discover whether the training it is giving is the sort that proves of greatest help under actual field conditions. It may be that the proof of the pudding will be the indigestion following its ingestion; but even if this be the case, it is better to find out what went wrong and try to discover a remedy. In other words,

the teaching of health education should be eminently practical. The ivory tower approach, if used at all, should be restricted to those few selected individuals who may be trained for complex research in health education problems.

If close contact with health education graduates is important for schools of public health, frequent check-up with employing agencies is possibly even more so. The employers are in a position to indicate whether or not they are getting the service desired from the health education workers in their organization. It is entirely possible that the employers do not know precisely what they ought to require. Would it not be possible and desirable for the schools of public health to assume a little more responsibility in helping to show the employing agencies what they really should have in the way of trained health educators, and what results may be expected if such people are employed? In this line of thought, Riggin⁶ has suggested, as a health officer, some ways of evaluating health education work. He says, "The quality of such activities can readily be measured by the editorial acceptance of the syndicated press of news releases, by the reader reaction to the departmental publications prepared for popular consumption, by the listener appreciation of departmental broadcasts, and by response to platform presentations." Additional methods of evaluation are available and should become more widely used.

There is another approach which public health schools can use to advance health education ideas among health administrators of the country. During their formal postgraduate training the future administrators may be given a picture of the health education field. It is a fairly widespread opinion that certain public health schools put a great deal more emphasis on health

education than others. This is inevitable, due to variations in faculty backgrounds and interests. While it is desirable for some schools to do an outstanding job in certain fields, as others develop their reputation along different lines, too much specialization is undesirable.

After graduation the various types of public health professional workers are going to have to work together whether they like it or not. And coöperation on the job can begin in no better place than the school of public health. A person who has learned to work with others in related fields is going to be more useful than someone with the most refined training possible who has never learned coöperation, and who cannot see things from other viewpoints than his own.

Suppose an embryo health officer with all his medical background and hospital experience does cringe when he has to sit through seminar sessions in which the budding health educator fresh from college struggles to find expression in medical terminology. Is it not likely that such a future health officer will be more conscious thereafter of the difficulty the public has in understanding Greek and Latin names? And will not the health educator who rubs elbows with the health officer in training have a more complete knowledge of how his mind works; why he needs to think of budgets and appropriating bodies; why his interest in public reaction to some bit of health education or propaganda may be somewhat different from the interest of the health educator? Perhaps of even greater importance in the training process is the advantage to health officers who will work in jurisdictions so small as to be unable to afford specialized health education workers. Such men can get at least an idea of what the health educators are trying to do, and some conception of the methods by which the objectives

are supposed to be accomplished. From this contact they may well acquire enough to be of the greatest value to them in their future work.

Public health schools should not allow prospective health educators to lose sight of the importance of private practitioners of medicine and dentistry in any community educational program. To his patients, the opinion of the physician is vitally important. He can either assist in the community program or can do much to discredit it if he has the feeling that it is ill-conceived, or even if he does not understand it. Mary Connolly⁷ has said:

There probably is no better investment of health education funds to be found than that intelligently planned to keep physicians informed. The personnel of the organization is expanded a hundredfold by each physician who recognizes his part in the field—if we are to elicit the interest of physicians, we must keep them informed as to the problems of the community; we must ask their advice in solving these problems.

Riggin⁸ has also pointed out the important place which organized medicine plays in the health education program.

As a means of increasing the usefulness of the specialist in health education perhaps a closer coöperation with the state medical society could be developed. This organization can be one of the most powerful educational influences in a state.

During their postgraduate training health educators can be given some contact with the local and perhaps the state medical society. Even attendance at meetings will give an idea of the problems of organized medicine and some of the attitudes to be found among its members. This is a force with which to reckon, even though the educator might not agree with all of the opinions expressed. It would not be impossible for the school of public health to coöperate with the local medical society in some program of community education, using students to

assist in preparing material for speakers; possibly in working up topics for newspaper articles and radio addresses, and in various other ways. Such a coöperative arrangement would offer difficulties, but might have very useful consequences. Whatever method the school may determine upon as best adapted to give the student the point of view of the private practitioner, the objective is worthy of considerable effort. The medical associations are doing a great deal of valuable work in health education, and this is one field in which there is likely to be little argument about the encroachment of health agencies into the field of private practice.

It is a bit difficult to say why a health officer is called upon to present the point of view of the schools of public health in this training problem. Possibly he may be compared to a baseball catcher who, standing behind the plate on the receiving end and close enough to the batter to observe him minutely, is allowed to signal the pitcher what kind of a ball to throw. Doubtless, it is helpful for the schools to get ideas from the field so that they may know the needs more completely, and therefore be in a better position to adjust their training programs to meet such needs as may be found to exist.

It is evident that the war has an effect on the training of health educators. The work they are to do upon graduation is more needed than ever before. Some details of the educational technic will need revision in accordance with the prevailing psychology of the public. The training period will perhaps require acceleration. Just as in securing candidates for schools of nursing, it is probable that some financial inducements may be needed to lure prospective students from the immediate appeal of high paid defense jobs. But fundamentally the needs are little different from those of peacetime. It is fortunate that thinking is crystallizing so that the master design will not have to be changed radically, and the training process may proceed apace.

The Preparation of Health Education Personnel for the War and Post-war Periods*

Supervised Field Work

LUCY S. MORGAN, PH.D., F.A.P.H.A.

Professor of Health Education, University of North Carolina School of Public Health, Chapel Hill, N. C.

COLLEGES and universities throughout the country have accelerated and modified their educational programs to meet the ever increasing demands of the war and post-war periods. Health education is one of the fields in which the need for intensified training has been felt and in which many changes are taking place.

Supervised field work is not new to many professions. For years the doctor, the nurse, the sanitarian, and the social worker have had "internships" included in their training. But only recently has need for such training been felt in the field of public health education. Some students^{1, 2} who were working on special thesis problems have had an opportunity to serve as "interns," but until this year no school of public health required field training for all health education majors.

In a recently published report on the Educational Qualifications of Health Educators³ it is stated that "carefully planned and supervised field experience and 'internship' should be regarded as an important element in the training of

the health educator and in the development of skill and ability in the field of health education." The same report also mentions the place for graduate training and recommends "that programs of professional study in health education be offered in those institutions which are providing professional education in other fields of public health, and which have available the required instructional facilities. Field training stations are desirable."

Thus field work has been officially recognized as an essential part of the health educator's training, but to date so little has been done along this line that it was felt that a description of an actual program would be worth while.

The field training program for public health educators which I shall describe here is part of a health education program that began in September, 1941, when the U. S. Public Health Service, in coöperation with the North Carolina State Board of Health and the Cumberland County Health Department, inaugurated the first of a series of demonstrations in community health education in extra-cantonment zones.⁴ Since that time, similar programs have developed in seven war counties in North Carolina, in one in South Carolina, and

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

in one in Oklahoma, and at the present time plans are under way for beginning them in many other states.

Health education consultants were loaned by the U. S. Public Health Service to the states mentioned to assist with the development of these programs.

These demonstrations created such an interest in community health education that there was an immediate demand for qualified health educators to develop similar programs in other areas. The demand for such personnel so far outnumbered the supply that several states decided to train their own workers. Provision was made for this training through Social Security funds, and qualified educators were recruited and sent to schools of public health for graduate training in public health education.

In addition to the state fellowships offered, the W. K. Kellogg Foundation made available funds to the U. S. Public Health Service in January, 1943, for training twenty health educators.⁵ The School of Public Health of the University of North Carolina was selected as the first training center because the counties in which the community health education demonstrations were being carried on were available as field training centers for health educators from this school.

The curriculum for majors in public health education at the University of North Carolina includes three-quarters of academic work and one-quarter of supervised field work or "internship." Formal courses in public health included in this field of study are: public health administration, epidemiology, vital statistics, sanitation, industrial hygiene, nutrition, venereal diseases and their control, tuberculosis control, bacteriology, parasitology, public health education, problems in public health education, school health education, and mental hygiene. In addition to these strictly public health courses other

courses required for majors in public health education are: social science, education, and public speaking. Students may also audit any course in the university that they think may be beneficial to them.

In setting up the curriculum for health educators an effort was made to provide a course of study that would give the educator a thorough understanding of the field of public health and at the same time train her to perform the functions of the health educator. (The best statement of these functions was recently set up by the Committee on Professional Education of the American Public Health Association.³)

Before the students go into the field they are given special preparation for their field training in a three-quarter problems course in health education. In this course the students work in groups and are asked to find solutions to many of the practical problems that they will meet in the field. Perhaps more important than the actual solution of the problems themselves is the fact that members of the group learn to work together and learn the methods and technics that they must later use with community groups.

The field training program for the first twenty-seven health education majors at the University of North Carolina began in June, 1943, when these students attended an "Institute for Tuberculosis Workers" arranged and conducted by the National Tuberculosis Association and the North Carolina State Tuberculosis Association for the secretaries of local tuberculosis organizations in the state. This institute was held at the headquarters of the North Carolina State Board of Health at Raleigh.

Participation in this institute gave the health education students an intimate knowledge of the objectives and operating program of a voluntary

agency on the national, state, and local level. While in Raleigh the students also visited the offices and laboratories of the State Board of Health and were given an opportunity to learn at first hand about the program and activities of the various divisions of this official state health agency.

From Raleigh each student proceeded to the field training center to which she was assigned. These centers are located in Cumberland, New Hanover, Craven, Carteret, Wayne, Lenoir, and Richmond Counties in North Carolina; in Spartanburg County, South Carolina; and in Pottawatomie County, Oklahoma. From one to four students were assigned to each center, the number depending upon the size of the community, the stage of development of the existing health education program, and the opportunity that the community offered for the student to get the greatest amount of experience in community organization.

The counties where the training centers are located are war counties that are faced with all of the problems that have arisen in such areas—concentrated populations, housing shortages, inadequate nutrition, overcrowded and insanitary eating establishments, prostitution, juvenile delinquency, shortage of nursing, medical, and teaching personnel, industrial hazards, and all of the other problems that have been mentioned many times during this meeting.

In the field training center a two weeks' orientation period was planned for the students by the Health Education Consultant on the staff of the local health department. During this time each student was given an opportunity to meet the entire staff of the health department and to observe their activities. Arrangements were also made for students to meet the heads of all of the agencies in the community that made any contribution to the total health program and to discuss with these leaders

the objectives and operation of their programs. After this orientation period the student officially assumed the responsibility of a health educator, with a special assignment for the weeks that remained in this phase of her field training program.

Excerpts from student-reports illustrate the type of work carried on in the assigned areas. One student gives the following outline:

Orientation—During the first month we spent a greater portion of our time getting oriented to the health department. We read the daily reports of the health educator, the appraisal form for the county health department, and available materials on state and local statistics and activities. We also made many contacts with local people in connection with organization work.

Organization and Committee Activity—The following aspects of the Executive Committee of the Community Health Education Program were developed. The trainees attended two regular committee meetings and one subcommittee meeting.

1. A review of the committee organization.
2. Introduction to committee members.
3. Report of the library committee on selection of books for school and public library. The books cover topics of venereal disease, social hygiene, and juvenile delinquency. Two hundred dollars has been allotted by the school board and health department for the purchase of the books.
4. Announcement of offer to the committee for radio time by the county medical society.
5. Discussion on garbage disposal in the city.
6. Committee discussed plans for organization work to be done by student trainees from the University of North Carolina.
7. Suggestions for radio programs to be presented by the student trainees were discussed.
8. At the second meeting a report of the radio topics was made.
9. A meeting date for the health council being formed was arranged.

Subcommittee Meeting—

1. Made selection of clubs and organizations which would be invited to have a representative on the Health Council.
2. Suggested that trainees open organization work in one of the school areas.

Organization Among the Colored—

1. The trainees were introduced to the com-

mittee of the Community Health and Defense League and heard a review of their organization and the aims and objectives they had set up.

2. The block leaders were appointed and began their first work by collecting money for the recreation drive. With a goal of \$100 set, \$63.86 was collected and turned in to the Chamber of Commerce and a recreation area was opened in the colored section.

3. Plans were made for a clean-up campaign when the subject of sanitation was selected for study by the executive committee. The campaign opened with an educational week with district meetings, film showings, and discussions by members of the executive committee and health department personnel.

4. The first home nursing class among the colored was started with 22 enrolled. The interest was stimulated through the activities of the executive committee.

5. Continued making contacts during this period and discussing the recreation drive and plans for the campaign with block and district leaders.

Recreation Program—

1. Interviewed the chairman and three other members of the park and auditorium committee of the recreation council. Wrote and presented a broadcast on the program.

2. Toured the parks with the supervisor and made plans for an in-service training program for the park supervisors. The supervisor offered \$10 for supplies.

Materials, Publicity, etc.—

1. Prepared notices for colored churches and wrote two news articles on meetings attended.

2. Learned to run a selectro-slide machine and a Bell and Howell machine and reviewed films from the State Department.

State Department Visit—

1. Visited the bureaus of the State Health Department. Checked out films and books from the department. Had conferences with the State Health Officer and with the Director of the Division of County Health Work.

Another student puts into her description what the program meant to her.

Two months in this county—what does it all add up to? Statistically it adds up to 30 meetings of various kinds, 128 pounds of rat poison, a TB exhibit, etc.; but these are the tangible results which are easily totalled in a statistical report.

What of the things that can't be found in

columns of figures—things like the worried look on a little colored boy's face when he asks whether he should have a Wassermann every week—things like the feeling you get riding home through miles of big pine trees under millions of stars, after swatting mosquitoes for an hour and showing VD films to 100 darkies, fresh from the potato fields! Somehow, these are the things that make it all amount to something worth while, and not just another job done!

Coming from an industrial city and a rather sophisticated atmosphere, I really didn't think I'd like living and working in a small, rural community—of course I could do it, but I did expect to be a little bored! To my amazement, I found I just loved every minute of it, and had a wonderful time along with it all. True, many of the people are backward and slow to accept new ideas, and, being a Yankee, I wanted to put a firecracker under them, but those who are convinced that a thing is good are so coöperative and really go out of their way to be helpful.

Working in a small health department was a grand experience, for it was easy to see what each person's job was and how it fitted into the whole health program. We were especially fortunate to be in a department that really coöperated, and with a health officer who was progressive and public health minded.

The biggest revelation to me, however, was seeing the real poverty of the South and the crying need for public health work. Many of the groups with which we worked were very appreciative, but I think I got the greatest personal satisfaction from the colored meetings. There is an earnestness and sincerity about them—even the primitive farm group at the river—when they are trying to learn something, that is touching. One couldn't sit there in the old colored church and watch the darkies file in after a long day's work in the fields, in some of the most outlandish outfits, and realize that people had come to learn something, and that it was up to you to give it to them without feeling part of some larger movement—something much bigger than just social service or health education. Guess it was just that feeling of what democracy is really all about—the more fortunate sharing with the less fortunate for the common good.

Somehow, out of it all, I got the feeling that for the first time I was really pulling my own weight in the world and doing something that was worth while that I could look back on with satisfaction in years to come. And I'm not ashamed to admit that I felt really touched when at our last colored church

meeting the minister said "God bless the health officer and the health educators!"

After an 8 weeks' training period in a community, the students were sent to the headquarters of the American Medical Association in Chicago, where they were given a week's orientation course on the health education program of the American Medical Association and on some special types of health education carried on by other agencies. The topics covered in this phase of the field training are as follows:

General Description of Purpose and Activities of American Medical Association

Health Education in Industry

The Radio Industry and Health Education

Health Meetings and Speakers

Motion Pictures

Because visual aids are important tools for carrying out any health education program and the health educator must know how to prepare, use, and evaluate them, arrangements were made for the students to receive some intensive instruction in exhibit making at the Cleveland Health Museum.

While this phase of the program concluded the summer field training for the health education majors, they will not actually complete their course until they have participated in an orientation course which will be given late in December at the National Institute of Health and the headquarters of the U. S. Public Health Service.

From the results of this supervised field work, those most closely concerned with it believe that field training should

give the students: (1) an appreciation and understanding of the contributions which many agencies and organizations can make to the total community welfare and to the total education program; (2) an accurate understanding of the ways in which these groups function and of how they have worked out their relationships to each other; (3) flexibility in thinking about problems to be solved so that when one way does not work others may be tried; (4) an understanding of how to make a program of work that gives time and emphasis to projects in proportion to their real importance; (5) a sense of the importance of timing in a program of community organization; (6) supervised experience in working with people so that special abilities are recognized and weaknesses overcome whenever possible.

From the point of view of the supervisor, field training is important to her because it enables her to find out what the student can actually do on the job and what sort of a person she really is. In other words. Is she sensitive to other people's feelings? Does she see her place in relation to the rest of the staff, to the program in which she is working, to the community, and to the chief?

How well does she stand up under pressure? Is she ingenious in a difficult situation? How well can she apply what she knows about health education? How well can she organize her own personal program of living? Can she get an over-all view of a situation, or does she tend to get lost in details? What are her outstanding personality patterns?

In supervised field training, therefore, both student and supervisor gain these understandings and insight best in a situation where the student has, (1) a real assignment for which she has actual responsibility; (2) a staff position (with a name and title) which gives her

definite status in the community; (3) freedom to think for herself, find and utilize resources, carry out her ideas, and evaluate the results of her efforts; (4) local supervision that helps her to make the best possible use of the training experience and at the same time give the best service of which she is capable to the coöperating community.

It is noteworthy that such field work as has just been described will become a part of the health education curriculum in two other schools of public health beginning this fall. With this increased interest in the training of public health educators it is expected that

a much larger well trained health education personnel will soon be available to assist with public health programs for the war and post-war periods.

Cleveland Health Museum Receives Substantial Endowment

The Cleveland Health Museum, Cleveland, Ohio, has become the recipient of trust funds established by Elisabeth Severance Prentiss in 1939. The Museum shares with several other institutions in the distribution of about eight million dollars, of which 5 per cent is set aside for the Cleveland Health Museum. According to the announcement, this is believed to be the largest sum ever set aside by an individual for purposes of health education. It is expected that the income from

these funds will provide in perpetuity about one-third of the present annual expense of the museum, which represents the amount of the former annual contributions of the late Mrs. Prentiss. The Museum has received a gift of the residence occupied by Mrs. Prentiss for a Museum site. Through a provision in the will, the Prentiss Foundation is able to receive contributions of others who may wish to support the Museum. Bruno Gebhard, M.D., is the Director of the Museum.

Preparation of Health Education Personnel for the War and Post-war Periods*

Preparation of the Public School Teacher

RUTH E. GROUT, PH.D., F.A.P.H.A.

Department of Preventive Medicine and Public Health, The Medical School and the College of Education, University of Minnesota, Minneapolis, Minn.

THE preparation of the public school teacher for health education has long been recognized as important. As far back as 1839, Caroline Beecher of Hartford Female Seminary wrote in an essay on *The Profession of a Woman*:

What is the profession of a woman? Is it not to form immortal minds, and to watch, to nurse, and to rear the bodily system, so fearfully and wonderfully made, and upon the order and regulation of which, the health and well-being of the mind so greatly depends?—Have you been taught anything of the structure, the nature and the laws of the body, which you inhabit? Were you ever taught to understand the operation of diet, air, exercise and modes of dress upon the human frame? Have the causes which are continually operating to prevent good health, and the modes by which it might be perfected and preserved, ever been made the subject of any instruction?

Two major wars have been fought since Miss Beecher's day, wars in which many lives were needlessly lost through sickness and disease. Today, in the throes of the worst conflict the world has ever seen, we turn to the teacher for his share of help in community-wide efforts to provide the nation with man power physically and mentally

capable of carrying on effectively in the armed forces, and in industry, agriculture, and community services. The brunt of the load in the immediate emergency will necessarily fall on teachers at the secondary level whose students are a most important source of wartime man power. It would be shortsighted, however, not to recognize the indispensable rôle the elementary teacher must play in laying the foundations of good health in the on-coming generation. Moreover, it is safe to say that in the present and post-war periods, both elementary and secondary teachers will participate more actively in efforts for general community health improvement, not only as an essential part of their primary task as teachers of children, but also because of the growing recognition of their potential value as lay leaders in health education. Sound preparation is essential if they are to perform these important responsibilities effectively.

In recent years much encouraging progress has been made in the field of teacher education in health. Significant developments have taken place, many under the leadership of members of this group, with the result that the general level of both pre-service and in-service training has been appreciably raised.

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

Despite the progress made throughout the country as a whole, teachers and school administrators remain inadequately prepared for participation in school and community programs. This has been shown clearly in such reports as Dr. Earl E. Kleinschmidt's recent study¹ in which is summarized the status of representative health instruction programs in twenty institutions in various parts of the United States.

In the teaching profession as in public health, the war has intensified many personnel problems. According to data assembled by Dr. Benjamin W. Frazier of the U. S. Office of Education, teacher turnover has doubled since our country entered the war. Many married ex-teachers and older teachers, long out of service, are returning to replace teachers who have entered the armed services or turned to more remunerative jobs in war industry. Contrary to popular opinion, the greatest number of actual vacancies are in junior and senior high school grades. "During the past two years," according to Dr. Frazier, "there has been a decrease of one-third in the enrollments of students in the teachers colleges and normal schools, and almost as large a decrease in the schools of education in the universities." There is, moreover, "a growing lack of interest in teaching on the part of students."² These facts force us to approach the whole problem of teacher preparation critically in an effort to seek methods which are applicable under wartime conditions. We need teachers able and willing to do the job now, and we must find ways of giving them the essential preparation. This is particularly true in the secondary field where teachers are least prepared and the health problems are especially acute. Because of the urgency of the secondary problem, this discussion will be limited to an exploration of what seem to be practical and expedient approaches to the health education

preparation of secondary school teachers in the present war period.

Preparation of teachers, as of other personnel, should be based on the job to be done. As previously indicated, in wartime the first job of the secondary field is to "make the greatest number of pupils physically (and mentally) fit to carry on as members of the armed forces or as efficient workers." At the same time it should prepare students to be intelligent citizens, ready and capable to work for their own and their community's health improvement. This will require both health guidance of individual students and group instruction.

A Committee on Wartime Health Education for High Schools, appointed by the U. S. Commissioner of Education and composed of representatives from the Army, the Navy, the Public Health Service, the Children's Bureau, the Office of Education, and representatives from the field has attempted to define the job more precisely in a recently published health education manual for high schools.³ This committee saw the task as student education in regard to correction of impairments, prevention and control of disease, better nutrition, accident prevention and emergency care, daily program planning for effective living, and sound mental attitudes. In addition, it saw it as one of giving students special health preparation for meeting intelligently and sanely the health and safety hazards or problems associated with military, production and community services.

It was the committee's belief that direct health teaching is essential as well as health instruction in connection with other school activities and subject matter fields. Moreover, health education in the school must be identified closely with other phases of the community health program if it is to be effective. This is a job which requires

a leader within the school well qualified in the field of health, and contributions from all members of the school staff, as well as from health departments, medical groups, parents, and others in the community.

Teacher education for health in the secondary school, therefore, means education of (1) teachers or other school personnel who will be capable of taking health education leadership and doing health teaching; (2) administrators who can intelligently shoulder the responsibility of putting a health program into action, and (3) all other school personnel who can make a contribution to the total program, as teachers of physical education, science, home economics, and social studies.

In the present emergency, this education cannot depend entirely on either the longer procedure of pre-service training or in-service training through the usual pattern of summer courses and graduate study. Even if it would, the teachers who could benefit most by further study are likely not to seek it unless some stimulation is given or special financial provision is made. Even with such assistance at hand, reports from the field indicate that suitable recipients for aid in advanced study are increasingly hard to find in this war period. The situation, then, it seems to me, indicates that in addition to usual preparation methods, in-service training programs for teachers on the job should be developed more extensively—programs which will reach first of all the key teachers of the school who are the best qualified to prepare for greater leadership and for health teaching responsibilities, and then as many others as possible. It also involves the utilization of every possible channel to arouse interest and support of administrators. Fortunately, there are many teachers and administrators who already have fine preparation and are doing excellent work in health edu-

cation. It is for the great majority of unprepared teachers that these suggestions are primarily designed.

In the spring of 1943, as a result of demands from the field, a second committee was called together by the U. S. Commissioner of Education to study the problem of the health preparation of school personnel, particularly in the secondary field. Membership on this committee was named by leading professional associations in education and health. The following methods of in-service training were proposed and developed in detail by the committee in its report⁴:

1. Staff or group conferences for discussion of health problems of students and community.
2. Study of health conditions or health education programs. Some problems suitable for study are:
 - a. Environmental factors
 - b. School lunch problems
 - c. Evaluation of health education
 - d. Curriculum study
 - e. Surveys
3. Reading and reference materials
4. Discussion and study groups
5. Local or regional workshops
6. Participation in various health activities, as in the health education activities of the school and community or through observation and field work.

These methods are suggestive only. Their chief merit lies in the fact that they were determined jointly by leaders in education and health and are based on practical procedures which already have proved effective through field experience. In the last analysis, the responsibility for sound teacher education rests in the states and local communities themselves, and it is hoped that no opportunity will be lost during the coming months to exert such responsibility.

The simplest approach to the in-service preparation of teachers is through a planned program in a single school. This program might be initi-

ated in any one of several ways. Perhaps one teacher, or more than one, has shown an interest in health and is seeking further help or a chance to be of greater service. The principal, the nurse working in the school, or some other member of a health staff may discover this interest and give assistance in the form of literature, professional advice, or opportunity for participation under supervision in some school or community health project. Even the busiest administrator or health worker should be able to find time to open up new opportunities for these teachers. Many helpful ideas in this connection are contained in the committee report on teacher preparation to which reference has just been made. This is a natural approach but its potentialities are often missed because it is commonplace and unspectacular. Interest of a few teachers may spread to others and give the principal encouragement to plan for a more extensive in-service training program.

A second, and more organized procedure for a single school would be for the principal to hold staff or group conferences for a discussion of school or community health problems and for the formulation of plans to meet these problems. A point of departure for such discussions, as the committee suggests, might be the ideas contained in the manual *Physical Fitness through Health Education*, or it might be some particularly urgent school or community health need which has aroused the concern of teachers. A third way may be through the formation of a health committee to deal in a more organized manner with special school health problems. This single school approach is especially suitable in an area where a modest start is desirable to demonstrate what can be done in health education, or where there is no full-time health educator to help plan a more comprehensive program.

Regional, county, and city-wide training programs, aided further by state supervision and state or federal support will be needed on an extensive scale if the important wartime health needs of students are to be met. As suggested previously, an attempt might first be made to bring together in natural working units the teachers who have been selected in each school to take leadership in health education. This plan has been tried in a number of places and is being contemplated in at least one large New England city in connection with a community-wide health education program. A few years ago in Cattaraugus County, N. Y., for example, delegated teachers from four experimental high schools met three or four times a year, and during the remainder of the time functioned as separate school committees. The larger group was organized originally to work out plans for the improvement of health education in the county. Among the activities it carried out which were especially educational for the members of the group were: preparation and use of survey forms for the study of pupil, school and community health needs; making and carrying out of plans to improve conditions found by these surveys; consultations as a group with members of the local health department; and study of health services available in the county. Teachers who had had previous preparation and were already well qualified in health education became the natural leaders of their respective school groups.

Appropriate problems for similar groups to consider now are: the part education can play in meeting health needs of students engaged in war work; providing pre-induction health training for young men and women soon to enter military services; and helping solve community health problems accentuated by the war. For example, if such a group found that students are needed

for the care of young children, for assistance in clinics, or for some other community service, the group might work out plans to give students the essential health preparation, and assemble materials needed in such a program. This would require extensive reading, consultation with professional health personnel, or other preparation which could become a worth while educational experience for the teachers.

A slightly different and more organized approach would be to have school health personnel, local health departments, or other community health groups offer their facilities and personnel for short courses to be given during the year in out-of-school hours with perhaps a certificate granted to show satisfactory completion of the work.

Possibilities for more comprehensive study and service programs as through extension, correspondence, and field courses, or in workshops and institutes should be fully explored with nearby teachers colleges and universities, and with state departments of education and health. Experience which others have had with these different training methods should be utilized. It is impossible at this time to describe the many pioneering programs which have been attempted. A brief mention can be given to only a few which seem to have special implications in wartime, namely, the community workshops conducted by the University of Michigan⁵ and the University of Kentucky in local communities to serve primarily the local teachers; the short institutes for teachers or administrators held under the sponsorship of such groups as Massachusetts Institute of Technology,⁶ New England Health Education Association,⁶ Teachers College, Columbia University, and the Center for Continuation Study at the University of Minnesota; the extension and summer courses supported by the state departments of education and health and the universities

or teachers colleges in Tennessee, Michigan, North Carolina,⁷ and Oregon; and the special institute and field service program in malaria education conducted by the U. S. Public Health Service.

The growing tendency of teacher preparation institutions to serve as centers for the guidance of educational programs in their respective localities has significance in respect to the problem at hand. What is needed now is further experimentation under state and federal leadership in the development of coöperative plans between these institutions and local departments of education and health.

Well qualified teachers who have had the benefits of further preparation may be used for wider service than in their own schools alone. In Cullman County, Ala., for example, a high school science teacher who had received advanced education in health, and had helped in the development of an excellent health program in his own school, was recruited by the county superintendent and county health officer as a part-time health education consultant for the other high schools in the county. In Tennessee, selected teachers who have received scholarships from the State Department of Health for summer study in health education at the university, have returned to their local communities and have made outstanding contributions not only to health improvement within their own schools but in the community at large. Some have been instrumental in securing new health units for their counties. A few have been appointed as full-time health educators in county and city systems.

Little has been said here about the preparation of school administrators for their responsibilities in health education. Concerning the importance of this, Dr. C.-E. A. Winslow has stated, "The inclusion of a comprehension of the significance of the school health program in the preparation of school

administrators is a major need. As long as such comprehension is lacking, the program will inevitably fail to reach its goal."⁸ If administrators now in service are given a chance to help in the development and extension of community-wide health education programs during this war period, they will grow, I believe, in their ability to put more effective programs into action.

There is every indication that the need for teacher preparation in health education will not have diminished in the post-war period. New and even more complex problems are likely to develop which may require different training procedures. Experience gained now through the application of the principle of building a teacher education program around the job to be done under existing conditions should prove of value in the future.

Pre-service and in-service education of teachers and administrators may be expected to expand rapidly in the post-war period. Teachers colleges and universities, in coöperation with local school systems and health departments, should begin now to plan for more dynamic institutional and field programs for the health preparation of teachers.

Professional community health educators will be in greater demand if the

impetus now being given by the U. S. Public Health Service and other groups continues. Well prepared teachers who have shown their ability in school and community leadership may become important recruits as such workers in the future.

Adequate health preparation of the public school teacher will bring rich dividends to the school and community. Public health has a vital part to play in this preparation.

Multiple Antigens for Active Immunization*

IN response to numerous requests, a Sub-Group on Multiple Antigens has been appointed under the Subcommittee on Evaluation of Administrative Practices, Dr. Haven Emerson, *Chairman*. The report is published herewith at the request of the committee.

Among the possible modifications in specific active immunization procedures which may contribute to administrative economy and efficiency, without loss of benefit to the individual to be protected, is the use of multiple or combined antigens. Military experience and a number of controlled field tests have in the past few years pointed the way to changes in civil health practice which may have merit, for application by the private physician and in the routine protection of child and adult groups in the community under the auspices of local or state health departments.

The Committee on Multiple Antigens was appointed to consider the present state of scientific knowledge and practical experience in this matter and to encourage or undertake such field tests as it might think desirable.

The following report, the result of the committee's deliberations since its organization, is approved by the Subcommittee on Evaluation of Administrative Practices, and by the Committee on Administrative Practice, and is offered as a statement of fact and opinion to serve as a basis of policy for health officers:

1. In the present state of our knowledge,

there is no urgent necessity for undertaking, as a wartime measure, an immediate special study of the reactions to the use of combined antigens among children or adults. Added information will become available during routine use of combined antigens. The immunizing effectiveness of such combinations of antigens as are considered desirable for routine use on the basis of practicability, already is supported by a considerable amount of data.

2. The optimal age for initial immunization, the optimal intervals between injections, and the optimal intervals before the renewal of immunization for the different antigens are variable and are important factors in the choice of possible combinations.

3. Combinations which are immunologically feasible should not be selected or recommended unless there exist justifiable reasons for establishing immunity with each antigen represented. Reasons considered justifiable are exposures which are apt to occur in normal civilian life, exposure due to occupation, or exposure due to special social conditions (for example, inmates of an institution).

4. In order to avoid confusion to those immunized, to parents, to clinicians, and to administrative officers, the combinations of antigens made available for use should be uniform in so far as practicable.

5. The influence of combining antigens on the potency of each component must be established prior to their use. Combinations which cause destruction or marked deterioration of an antigen are not considered suitable. The amount of

* Report of the Study Committee on Multiple Antigens, Subcommittee on Evaluation of Administrative Practices, Committee on Administrative Practice, A.P.H.A.

each antigen administered when given in combination must not be less than that required when administered singly.

6. Present experience indicates that non-living antigens combined with alum are better immunizing agents than non-living antigens suspended or dissolved in plain diluents. The proper spacing of the individual immunizing injections is of great importance in developing maximum immunity, as is also the route of the injection.

7. Information is at present sufficiently definite and convincing to justify the statement that immunization against scarlet fever as a routine or community-wide practice under official auspices is inadvisable until a more suitable antigen becomes available.

8. On the basis of the above impressions, the use of pertussis vaccine and diphtheria and tetanus toxoids, either singly or in combination, is considered acceptable prophylactic practice for the immunization of children in normal civilian life, except a pertussis-tetanus combination. There are other antigens, as for example smallpox vaccine, which must always be administered singly. Antigens intended to provide protection against special hazards may be administered singly or in combination, dependent upon the need.

9. Our present knowledge of immunization procedures through active immunization warrants the following recommendations:

a. *Diphtheria*—Administration of the prescribed dosage of plain or alum precipitated toxoid without preliminary Schick test, preferably not later than 6–12 months of age; otherwise as soon thereafter within the preschool age as possible. Repeat or booster dose on school entrance, sooner when indicated. Immunization of younger school children without the use of the Schick test is indicated if toxoid has

not been given during preschool life. Immunization of older Schick-positive children or adults when indicated. Special consideration of pseudo-reactors advisable after 9 years of age. Reactions to injections in younger children and persons not pseudo-positive are negligible. Pseudo-reactors should receive immunizing dose divided into several small injections.

b. *Pertussis*—Administration of the prescribed dosage of plain or alum precipitated vaccine at 6–12 months of age. Administration in later preschool ages, or over, less significant as a community practice under official auspices. Value of repeat or booster dose on school entrance not adequately established, though such dose at younger ages advisable. Approved strength of vaccine, 10 to 15 billion organisms per 1 ml., either plain or alum precipitated.

c. *Tetanus*—Administration of plain or alum precipitated tetanus toxoid by itself in the preschool group as a routine practice is not recommended. In combination with diphtheria toxoid, its use is approved in this age group. The administration of tetanus toxoid at any age is recommended, provided the environmental (social or occupational) conditions demand immunity. Experience is as yet not adequate to recommend the time of giving the repeat dose. The indications are that a booster dose in one year with a repeat booster dose at time of injury, provided injury is not more than 5 years after booster dose, will provide adequate immunity so that antitoxin need not be used prophylactically. Reactions to injections at all ages negligible with few exceptions.

d. *Smallpox*—Inoculation before 3 months of age or as soon thereafter

as practicable. Repeat on school entrance and at 5 year intervals as far as practicable. Revaccination upon exposure to active case essential under all circumstances.

e. Other Antigens of Recognized Value—Recommended whenever special circumstances demand such immunity.

State and Provincial Health Authorities Endorse Local Health Unit Plan

At the 59th Annual Meeting of the Conference of State and Provincial Health Authorities of North America held on March 22 in Washington, D. C., under the Presidency of J. Lynn Mahaffey, M.D., State Health Officer of New Jersey, the following resolution was unanimously adopted.

WHEREAS, the outstanding deficiency in public health administration throughout the North American continent is the lack of overall coverage by legally constituted local health organizations, and

WHEREAS, expansion in the field of public health demands that every segment of the

population must receive the benefit of full-time public health protection, and

WHEREAS, studies have been made by the Committee on Administrative Practice of the American Public Health Association for the purpose of evolving a plan for complete public health services, and said committee has reached agreements with the state health officers as to the desirable pattern for full-time public health units in 39 states, representing over 85 per cent of the population of the United States, therefore be it

RESOLVED, that the Conference of State and Provincial Health Authorities of North America urge the early implementation of such a program throughout the Continent of North America.

Chemical Warfare—A Chemical and Toxicological Review*

COLONEL JOHN R. WOOD, M.C.

Director, Medical Research Laboratory, Edgewood Arsenal, Maryland

IN reviewing very briefly the chemistry and toxicology of the war gases, military secrecy demands that my remarks be confined to chemical warfare agents already known to our enemies, and to data about these known agents which will not give them aid or comfort. This, of course, precludes discussion of newer developments, but there is much unrestricted information which may be unfamiliar and of interest.

Of the many thousands of poisonous substances known, only a few have the necessary toxicity, and chemical and physical properties to qualify them as effective war gases.

CLASSIFICATION OF WAR GASES

The chemical and physical properties of the war gases are of primary importance in determining how and when they may be effectively employed, and in predicting what the enemy may do with them. A simple but important classification of gases in this respect refers to the length of time they are effective. If they persist in toxic concentrations at the point of attack less than ten minutes, they are called *non-persistent* gases; if they are effective for a longer time, they are *persistent* gases.

The toxicological properties of the war gases must be known in great detail

in order that the proper gas may be selected to produce a particular effect, and in order to know what concentration of the gas must be put down on the target.

The war gases are classified according to their primary toxicological effects, as follows:

WAR GASES

1. Harassing gases
 - a. Tear gas (lacrimator)
 - b. Vomiting gas (nose gas; sternutator)
2. Casualty gases
 - a. Choking gas (lung irritant)
 - b. Blister gas (vesicant)
 - c. Blood and nerve poisons (systemic poisons)

The harassing gases are used to force the enemy to put on gas masks and to interfere at a crucial time with his effectiveness. These agents have only temporary effects and they do not kill, or even produce dangerous symptoms. The casualty gases are used to injure or kill.

TEAR GASES

The tear gases are all effective in very low concentrations. The most widely employed are the following:

1. Chloroacetophenone, $C_6H_5-CO-CH_2Cl$, is a white crystalline solid, which is volatilized either from burning or explosive munitions or sprayed as a solution in chloroform, generally mixed with chloropicrin. Once volatilized it is essentially non-persistent. It has a faint odor, somewhat like apple blossoms.
2. Brombenzyl cyanide, $C_6H_5-CH-BrCN$, is a liquid, which volatilizes slowly. The

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

commercial product is light brown in color. It is used as a liquid spray or in explosive munitions. It is moderately persistent and has a fruity odor.

3. Ethyl iodoacetate, $\text{CH}_3\text{I}-\text{COO}-\text{C}_2\text{H}_5$, a brown liquid, is less used. It smells like pear oil.

4. Recently, chloropicrin, $\text{C}-\text{NO}_2-\text{Cl}_3$, or nitro-chloroform, a pale yellow, volatile liquid, has been reclassified as a tear gas. It also causes vomiting and in high concentration it is an effective lung irritant, making it difficult to classify. It is often used in solution with chloroacetophenone. It is very irritating to the nose and has an odor somewhat like flypaper or anise.

The tear gases (or lacrimators) in low concentrations act almost exclusively upon the eyes to produce pain, blepharospasm, a flow of tears and temporary interference with vision. In high concentrations some also irritate and redden the hot sweaty skin.

VOMITING GASES

The vomiting gases are all crystalline solids and are usually dispersed as fine particulate smokes from burning munitions. They are effective in very small concentrations, but their smokes are non-persistent. They all smell somewhat like burning fireworks.

1. Adamsite, or diphenylamine chloroarsine, $\text{HN}=(\text{C}_6\text{H}_4)_2=\text{AsCl}$ produces a canary yellow smoke which fades to colorless as it is diluted by air

2. Diphenylchlorarsine, $(\text{C}_6\text{H}_5)_2=\text{AsCl}$

3. Diphenylcyanarsine, $(\text{C}_6\text{H}_5)_2=\text{AsCN}$, which produce white smokes, which become colorless on dilution with air

The vomiting gases induce at first a strong sensory irritation of the respiratory tract. The symptoms may be delayed a few minutes in their onset, so the victim may get a good dose of the gas before he knows anything is wrong. He then begins rather suddenly to cough, and in the course of a minute or so this becomes quite violent and uncontrollable. He feels as though his trachea was about the size of a balloon and as raw and irritated as a full blown acute tracheitis. He may sneeze some

and soon his nose begins to drip a watery secretion. He is quickly salivated, and feels depressed, weak, and ill. If he is severely affected, he will have nausea and vomiting and pain in his teeth and sinuses, particularly the frontal sinuses. These effects, as you may well imagine, make it difficult for the victim to wear a gas mask. A man fully affected by a vomiting gas looks and feels about as miserable as a human specimen can. Fortunately, however, in spite of his alarming symptoms, he is not seriously injured, and it has been demonstrated many times that he is still capable of strenuous physical exertion. If he can be induced by inspiring leadership to carry on, he can do so without injury to himself, and the effects pass off in an hour or two.

CHOKING GASES

The most important choking gases are phosgene and chlorine, both gases at ordinary temperatures and pressures, but are generally liquefied under pressure for storage in cylinders, shells or bombs. On opening the cylinders or bursting the explosive munitions, they rapidly evaporate to form a gas cloud, heavier than air. If conditions are right, that is, the ground as cool or cooler than the air and the wind very gentle, these clouds will drift along the ground in effective concentrations for several miles.

Phosgene, COCl_2 , is a colorless gas which irritates the eyes, nose, and throat. Its odor is difficult to describe, but it is probably nearer like that of very musty hay or crushed green corn-silk than anything else.

Chlorine, Cl_2 , is a greenish-yellow gas with a very pungent, irritating odor familiar to all.

The effects of these gases are predominantly upon the lower parts of the respiratory tract, particularly upon the terminal bronchioles. Their immediate action is to induce coughing, due to

sensory irritation, and a feeling of constriction in the chest and shortness of breath, due to bronchoconstriction. The heart is slowed and there begins very early a deficiency of oxygen in the circulation. The victim is usually uncomfortable, restless, and apprehensive. He develops a moderate temperature and may sweat profusely. A fair percentage of cases of poisoning by phosgene, however, recover from their initial symptoms after the first few minutes, and may then experience a feeling of well-being for possibly several hours, provided strenuous exercise and deep breathing are avoided. The bronchospasm, bronchiolar edema, and loosening of bronchiolar epithelium bring on a curious mixture of emphysema and atelectasis of the air sacs and cut down the functional capacity of the lungs. There follows, after a few hours, an outpouring of fluid into the alveoli, which seriously interferes with gaseous exchange and enormously accelerates the developing anoxia. The fluid lost into this lung edema causes a serious progressive hemoconcentration and slowing of the circulation. Some of the subjects during these stages exhibit a dusky cyanosis, peripheral venous congestion, and a rising blood pressure, known as the "blue stage." It is particularly common in chlorine poisoning. The "blue stage" may subside gradually and eventuate in recovery, or it may gradually or suddenly pass into the "grey stage" of circulatory collapse. Many cases of phosgene poisoning fail to go through a "blue stage," but pass directly into the "grey stage" of falling blood pressure and a series of symptoms closely resembling shock. The skin appears pale and waxy and is cold and dry. Breathing is hurried and shallow, and the pulse is weak and rapid. The victim is extremely weak, and fearful of impending death, until unconsciousness supervenes. Death is due to an intense want of oxygen by

the body tissues and a widespread interference with metabolic processes, which culminates in circulatory failure.

BLISTER GASES

The blister gases are all liquids which vaporize slowly to highly toxic vapors. There are three main classes of these gases:

1. The sulfur mustards, which are compounds, containing sulfur
2. The nitrogen mustards, which contain nitrogen
3. The arsenical vesicants, which are compounds of arsenic

Either the liquids or the vapors burn and injure any part of the body they contact. The eyes and respiratory tract are particularly susceptible, but the skin as well is reddened, burned, and blistered. When they are ingested in food or water, they violently irritate the gastrointestinal tract and produce all the attendant symptoms of pain, nausea, vomiting, and collapse. They attack any part of the respiratory tract, but the predominant effect is on the upper portion, particularly the pharynx, larynx, trachea, and bronchii. The ciliated cells of the respiratory epithelium are quickly killed and the whole bronchial tree is laid wide open to infection. Secondary bronchopneumonia is very common in the severe cases, and is responsible for most of the deaths. Direct injury may, however, be severe enough to cause death. Respiratory epithelium, exuded serum and leukocytic cells are shed from the surface of the trachea and bronchii as a coagulated, continuous, tenacious cast extending deep into, and plugging, the smaller bronchii and bronchioles. This plugging may so completely block the smaller air passages that the victim is suffocated. The term "cooked" best describes the appearance of the upper respiratory tract. Intense congestion of the lungs with moderate edema completes the terminal picture.

MUSTARD GASES

The only sulfur mustard which has yet been used is mustard gas itself, $S=(C_2H_4Cl)_2$. This was by all odds the king of war gases in World War I. It caused three-quarters of all AEF gas casualties, and three-quarters of the gas deaths.

It is an oily liquid, colorless when pure, but usually brown as employed in the field. Its odor is variously stated to resemble horseradish or garlic, but it stretches the imagination to note the resemblance. Its odor is quite characteristic and resembles nothing else very closely. It can be dispersed in a wide variety of explosive munitions, sprayed from airplanes, sprinkled on the ground from watering carts, or simply dropped from planes in large tin cans. It contaminates everything it touches and in heavy contaminations slowly gives off its poisonous, blistering vapors for days.

The chemistry of the nitrogen mustards is secret. They are all colorless or pale yellow liquids. Some are less persistent and some are more persistent than mustard gas. Their odors vary from fishy to practically odorless. They do not damage the skin as much as mustard gas, but do a first-class job on the eyes and respiratory tract.

Two great tactical assets possessed by the sulfur and nitrogen mustards are their insidious action and persistence. They produce no immediate pain or effects of any kind, and some have almost no odor. The victim may be severely or even fatally injured without knowing he is being exposed.

The degree of injury produced by a casualty gas is dependent upon the product of time and concentration of gas. Since the blister gases vaporize slowly and persist for a long time, they are effective in extremely low concentrations, provided the victim remains in the contaminated area long enough.

In investigating industrial and labo-

ratory accidents due to the mustards, one cannot help being impressed with the fact that the vast majority of the cases had no idea they were contaminated and being burned. Pain and reddening of the skin do not begin for some hours, long after the damage is done. Even liquid mustard in the eye is only mildly irritating for the first hour, yet the damage is irreparably done in the first five minutes.

Some of the nitrogen mustards are quite toxic by skin absorption and readily cause fatalities in animals. The bone marrow, spleen, thymus and lymphoid tissue in general are severely attacked and an almost complete leukopenia develops. This has not yet been observed in man from skin burns.

ARSENICAL VESICANTS

The arsenical vesicants are all organic dichlorarsines, and all are colorless to brown liquids. They all have sharp irritating odors, and lewisite smells strongly like geraniums. They all hydrolyze easily in contact with water or moist surfaces to yield the corresponding arsine oxide.

Lewisite, $Cl-CH=CH-AsCl_2$, or chlorvinylidichlorarsine, has been widely studied, but has not yet had war experience, unless the Japanese employed it against the Chinese. It is more volatile than mustard, and very damaging to the skin and eyes as liquid drops. It has a very low freezing point and can be used in cold weather when mustard would freeze. It can also be mixed with mustard gas to form a low freezing point mixture. It can be dispersed from explosive munitions or sprayed from airplanes.

The other three arsenical vesicants, called Dicks by the Germans and British, methyl Dick, ethyl Dick, and phenyl Dick, have all had limited war service in World War I. Methyl dichlorarsine, CH_3-AsCl_2 , and ethyl dichlorarsine, $C_2H_5-AsCl_2$, are fairly volatile,

and are usually dispersed as a vapor from explosive munitions. Phenylldichlorarsine, $C_6H_5-AsCl_2$, is a heavy oily liquid and quite persistent. Like lewisite, it forms an effective low melting point mixture with mustard gas.

In contrast to the insidious action of the mustards, the arsenical vesicants cause instantaneous excruciating pain upon striking the eye, with immediate blepharospasm. Stinging pain is felt by most subjects within 10 to 30 seconds after a liquid arsenical vesicant contacts the skin. Their vapors are likewise very irritating to the eyes and respiratory tract, which compels wearing of the gas mask. Their presence is therefore quickly obvious, and serious injury from them is proportionately less likely, if defensive measures are available.

The arsenical vesicants can cause very deep burns into the muscle and serious or fatal systemic poisoning by absorption through the skin in animals, because the animal is prevented from doing anything about it. No human subject has yet been so seriously burned or poisoned, however, nor does it seem likely to occur unless the victim is unconscious or defenseless.

BLOOD AND NERVE GASES

The third group of casualty agents is known as the blood and nerve poisons (or systemic poisons). Their local effects are minimal, and their poisonous properties are manifest only after absorption into the general circulation. There are a great many possible compounds in this class, and many have been investigated. I shall, however, refer to only two which have a record of war service.

The only one employed to any extent in World War I was arsine gas, AsH_3 . It is a colorless, inflammable, diffusible gas. In its highest purity it is odorless, but the commercial item smells strongly like garlic. It can be liquefied in mu-

nitions but special precautions are required to prevent it inflaming upon explosion of the shell. It can be generated at the target in wet weather by dispersing a suitable powdered arsenide, which reacts with water to liberate the arsine.

It acts in a number of ways in the body, widely inhibiting enzyme systems, but it manifests itself clinically chiefly by its striking effect upon the red blood cells. In severe cases it causes widespread hemolysis and much of the liberated hemoglobin is passed in the urine. Coagulated debris collects in the kidney tubules, stained almost black by the hemoglobin, and may eventuate in kidney failure, anuria and a uremic death. During the stage of hemolysis, the victim suffers chills, nervousness, exhaustion, and collapse. He soon develops anemia, and in the course of a few hours jaundice begins to appear. This may progress until he is deeply jaundiced. If he survives the hemolytic stage, he may then develop the typical symptoms of arsenic poisoning. As the gas was employed in World War I, however, there were not so many severe cases, and the mortality was very low—only one-half per cent.

Hydrocyanic acid gas was tried abortively in World War I and given up as ineffective. It was then technically difficult to build up crash concentrations of any gas, and this was particularly difficult to accomplish with a light diffusible gas like HCN.

It is a colorless, highly volatile liquid, boiling at $26.5^\circ C$. It is dispersed from explosive munitions as a colorless gas having a faint odor of bitter almonds or peach kernels.

Very low concentrations of HCN can be detoxified and eliminated without the development of any symptoms, but high concentrations are more rapidly lethal than those of any other known gas. The rapidity of onset of symptoms is practically identical with the

circulation time from lungs, through the heart, to the brain. The subject becomes confused, befuddled and dizzy in a few seconds. He is seized with an uncontrollable hyperpnea, the depth of respiration being particularly increased. Great weakness and muscular incoördination come on simultaneously and in 10 to 20 seconds the victim is unconscious and beginning to be seized with convulsions. Respiration stops in a half to three-quarters of a minute, except for an occasional gasp, but the heart continues to beat for several minutes. The chances of survival after respiration ceases are small indeed. HCN is almost wholly an "all or none" gas. The subject is either rapidly killed or he quickly recovers. There are, however, a few borderline cases who, as a result of prolonged anoxia of nervous tissue during the poisoning, either die slowly, or recover slowly, and may be left with permanent neurological damage quite analogous to that which sometimes follows carbon monoxide poisoning. The gas acts primarily to inactivate the cytochrome oxidase enzymes. Thus the blood, while itself fully oxygenated, is unable to supply the tissues, because the tissue cytochromes cannot utilize the oxygen. The venous blood is returned to the heart bright red in color and nearly as fully oxygenated as arterial blood. At autopsy these cases have a pink hue to the skin strongly reminding of carbon monoxide poisoning.

There are two other classes of chemical agents, the incendiaries and screening smokes, which may cause incidental injury to troops, but they are not used for that purpose. There are also other gases incident to war, such as carbon monoxide and the nitric oxides, which

may cause injuries or fatalities among troops, but they are not employed as war gases.

I should not like this brief discussion of the war gases to give the impression that these agents as employed in war are extremely lethal. On the contrary, the injuries they cause are many times less lethal than those due to other weapons of war. While they caused nearly one-third of all the AEF battle casualties hospitalized in France, they caused less than 10 per cent of the hospital deaths, the mortality being only 1.75 per cent, compared with a mortality of 8.1 per cent due to other weapons.

A very striking comparison is obtained if all those killed in action or dying before reaching hospital are included. The gas warfare mortality is then almost exactly 2 per cent, while that due to other weapons is 24 per cent, a ratio of 1:12.

Large numbers of wounded are a very serious encumbrance to an army. One of the chief tactical values of chemical weapons is their ability to produce large numbers of casualties with relatively few fatalities.

In closing, I should like to stress that there are no super-colossal war gases, of the variety that one drop on a dog's tongue will kill ten men. It takes very definite and large amounts of chemicals to build up casualty producing concentrations in open spaces. This requirement is so great that it seems most unlikely that our enemies could make more than a small nuisance chemical raid against the continental United States. The most likely supposition is that they will consider the benefits to be derived from such a raid not worth the cost and effort.

Tissue Cultures for Virus Investigations in the Field^{*†}

MAJOR M. SANDERS, MC, AUS, AND C. H. HUANG, M.D.

College of Physicians and Surgeons, Columbia University, New York, N. Y.

FLUID tissue cultures have been used for propagation of viruses since 1928 when Maitland and Maitland¹ initiated the use of their preparation. However, the effect on tissue viability in the fluid environment of ratio of tissue to fluid, pH of menstruum, and method of preparation of tissue have been investigated only in recent years.

That there has been a need for detailed studies is seen from the fact that the early preparations were so crude as to suggest complete destruction of tissue. In fact, Maitland and Maitland² reported that they were able to grow virus in the presence of non-living cells, a claim that was negated by Rivers, Haagen, and Muckenfuss,³ who demonstrated living cells in the Maitland cultures.

In previous reports⁴ the use of serum ultrafiltrate diluted with Simms physiological solution has been stressed because of the possibility that this protein-free product of ox serum is capable of maintaining viable tissue cells for long periods of time. Furthermore, such a fluid medium is well buffered and is convenient to handle in the labora-

tory. Maintenance of viability also depends on a low ratio of tissue volume to fluid volume, 1-100 or less, a pH range of 7.2 to 7.6, and the use of a closed culture system (rubber-stoppered flasks). In order to minimize damage to cells during preparation great care should be taken to use sharp instruments for mincing, and the tissues should be washed at least 3 times with decarbonated "Z" solution to remove intracellular autolytic enzymes.

The present communication will attempt to correlate certain information obtained during the course of investigating fluid tissue cultures in regard to virus propagation and to point out possible application of laboratory methods to field studies in virus diseases. Although this study covers a period of more than two years, only summarized or typical data will be presented.

MATERIALS AND METHODS

The various types of *field cultures* as described below consisted of minced chick embryo tissue in 2 ml.* of fluid medium in rubber-stoppered Wassermann tubes. The convenience of working in the field with tubes of this size,

* Presented at a Joint Session of the Epidemiology and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

† This work has been carried out largely under the auspices of the Commission on Neurotropic Virus Diseases, Board for the Investigation and Control of Influenza and Other Infectious Diseases in the Army, Preventive Medicine Division, Office of the Surgeon General, U. S. Army.

* It should be emphasized that larger amounts of fluid medium (and consequently more tissue) may be desirable for certain types of specimens. It is obvious, for example, that sputum can be studied in larger cultures (50 ml.). The amount of medium should vary according to the type of inoculum. In the present study 2 ml. lent itself to manipulation of small amounts of material.

which can be carried in one's vest pocket, is obvious.

At intervals during storage of these cultures, pieces of tissue were removed and plasma-patched in Carrel flasks to test the viability of cells. At the same time, varying amounts of virus were inoculated into the tubes to determine the degree of propagation of virus in cultures of different ages.

Daily observation under the microscope of the presence or absence of proliferating fibroblasts in the Carrel flask subplants made it clear whether or not tissue was viable. Such subplants were used because tissue suspended in a fluid medium will generally not proliferate unless a semipermeable coagulum is present for support of delicate cellular filaments. It may be noted that an embryonic cell may be *alive* without retaining a capacity for proliferation. Conversely, a cell may be in good morphological condition and not be viable. The test of ability to proliferate may be looked upon as a gross and positive sign of cell viability.

Culture Media which were compared consisted of 3 types: serum ultrafiltrate diluted with 2 parts of Simms physio-

logical solution, the physiological solution alone, and diluted serum ultrafiltrate containing a sulfadiazine mixture (9 parts sodium sulfadiazine and 1 part of sulfadiazine). All solutions contained either 2 or 5 mg. per cent phenol red so that the pH could be followed at all times. The pH range was adjusted carefully with 5 per cent CO₂ after the culture was completed and again whenever there was occasion to open the flasks. The formulae for the solutions and more specific details in handling them may be obtained from previous reports.⁴

Tissue—The tissue consisted of whole minced 9 day chick embryo. The eyes and claws were discarded and the tissue was finely minced so that the largest segment did not exceed 2 mm. in diameter. After at least 3 washings with 10 ml. of decarbonated "Z" solution, one drop of tissue was placed in the fluid medium. While it is difficult to state exactly how much tissue was placed in each tube, it should be noted that the tissue suspension is fairly uniform regardless of the amount of washing fluid since the container, usually a Petri dish, is tilted allowing the tissue to settle. The diameter of the pipette is approximately 3 mm. so that one drop of minced tissue is well within the range of the optimal 1-100 fluid to tissue ratio.

FIGURES 1 AND 2—Tissue from Serum Ultrafiltrate after 35 Days at Room Temperature in Tube Cultures (Note luxuriant growth of fibroblasts)

Virus — Equine encephalomyelitis virus (Western strain) was used for these experiments because it has been studied previously in serum ultrafiltrate⁵ and because it is representative of a group of viruses which can be grown at will and which are important subjects for field investigations. Although the virus was maintained in mice and in tissue cultures, only the latter was used as source of virus in this investigation.

EFFECT OF PROLONGED INCUBATION AT ROOM TEMPERATURE ($25^{\circ}\text{C.} \pm 7^{\circ}$)

ON THE FIELD CULTURES

As is apparent from Figures 1 and 2, tissues maintained for 35 days at room temperature were viable and capable of proliferation. This finding in respect to the majority of segments in the *field cultures* was repeated and confirmed on many occasions. Although longer periods of time were not tested routinely, there is on record a single instance of viability of tissue after 42 days at room temperature. This fact plus the constancy with which tissue viability could be demonstrated after 35 days, suggests that this interval is not a maximum.

When the physiological solution alone

was used without serum ultrafiltrate, tissue viability could be demonstrated only for much shorter periods of time, up to about 14 days (Figures 3 and 4).^{*} For periods up to 1 week it appears to make little difference whether one suspends tissue in physiological solution alone or in serum ultrafiltrate. However, it should also be noted that in serum ultrafiltrate cultures there is little variation in pH from culture to culture and the medium is so well buffered that the shift in pH under various circumstances is minimal.

EFFECT ON THE TISSUE OF VARYING TEMPERATURES

Inasmuch as one may expect in the field a greater variation in temperature than is found in a laboratory situated in the temperate zone ($25^{\circ}\text{C.} \pm 7^{\circ}$) the above experiments were repeated under more extreme temperature variations. Because serum ultrafiltrate had been demonstrated on the basis of plasma studies to be the superior tissue medium, study of the field cultures at refrigerator temperature ($+4^{\circ}\text{C.}$ to $+6^{\circ}\text{C.}$) and at 37°C. was carried out

^{*}A photographic record of 21–28 days only is available. From actual observation growth of cells in salt solution alone was sparse, irregular, or absent from 14 days.

FIGURE 3—Tissue from “x6” Physiological Solution after 28 Days at Room Temperature in Tube Cultures (Note absence of fibroblasts in the vicinity of the Explant)

FIGURE 4—Tissue from “x6” Physiological Solution after 21 Days at Room Temperature in Tube Cultures (Note rare fibroblast)

FIGURE 5—Tissue from Serum Ultrafiltrate after 22 Days at $+4^{\circ}$ C. in Tube Cultures

with this medium only. In brief, repeated tests showed that at 37° C. tissue remained alive for at least 4 weeks (Figure 6), and at 4° – 6° C. tissue viability could be demonstrated for periods

as long as 3 weeks (Figure 5). With respect to the latter finding it is interesting to note that cultures in which virus had been propagated at either incubator or room temperature have been placed in the refrigerator for several months with only gradual and relatively slight loss of virus potency. We have made use of this fact for maintaining "auxiliary cultures" which may be used for seeding purposes when contaminations or other accidents damage cultures.

FIGURE 6—Tissue from Serum Ultrafiltrate after 28 Days at 37° C. in Tube Cultures

TABLE 1

Comparative Potencies of Field Cultures of Varying Age (Virus Inoculum: One Drop of 10^{-4} Dilution of Virus-containing Culture Having a Potency of $10^{-4.3}$)

Type of Preparation	Incubated *	Age of Cultures at Time of Inoculation					
		1 Day	7 Days	14 Days	21 Days	28 Days	35 Days
Serum ultrafiltrate plus "x6" physiological solution (Simms)	Room temp.	$10^{-5.5}$	$10^{-4.2}$	$10^{-4.8}$	$10^{-4.0}$	$10^{-5.2}$	$10^{-4.8}$
Serum ultrafiltrate plus "x6" physiological solution (Simms)	37° C.	—	—	—	$10^{-5.2}$	$10^{-4.2}$	
Serum ultrafiltrate plus "x6" physiological solution (Simms)	Icebox	—	—	—	$10^{-3.0}$	trace	
"x6" physiological solution (Simms)	Room temp	$10^{-5.0}$	$10^{-5.2}$	0	0	0	0
Serum ultrafiltrate plus 50 mg. per cent sulfadiazine mixture in salt solution (Simms)	Room temp.	$10^{-4.6}$	$10^{-4.5}$	$10^{-4.5}$	$10^{-4.0}$	$10^{-2.8}$	$10^{-2.6}$
Serum ultrafiltrate plus 85 mg. per cent sulfadiazine mixture in salt solution (Simms)	Room temp.	$10^{-4.5}$	$10^{-4.5}$	$10^{-4.5}$	$10^{-3.5}$	$10^{-2.8}$	$10^{-2.5}$
Serum ultrafiltrate plus 100 mg. per cent sulfadiazine mixture in salt solution (Simms)	Room temp.	$10^{-4.8}$	$10^{-2.7}$	0	0	0	0

* Incubation and age of culture refer to culture environment before virus was inoculated. After addition of virus, all cultures were placed at 37° C. for 45 hours and were then tested for potency in mice.

CORRELATION BETWEEN TISSUE VIABILITY AND VIRUS GROWTH

As can be seen from Table 1, propagation of virus is closely correlated with tissue viability and even in 35-day-old room temperature cultures LD_{50} of $10^{-4.8}$ was obtained. Since Table 1 is a summary of experiments where the original virus inoculum represented one drop of the final dilution activity of culture used for seeding, it is clear that there was a significant increase of viral potency in the majority of instances where tissue viability had been demonstrated.

ADDITION OF A BACTERIOSTATIC AGENT TO THE FIELD CULTURES

Since the *field cultures* are intended for use in recovering virus from contaminated specimens in the field, the effect of adding a bacteriostatic agent to the fluid medium was investigated. For this purpose a sulfadiazine mixture was used (9 parts of sodium sulfadiazine plus 1 part of sulfadiazine) which was soluble and which did not cause a marked change in pH. Concentrations of 50, 85, and 100 mg. per cent of the sulfadiazine mixture were added to the cultures and studied at various intervals in a fashion similar to that de-

scribed in the previous sections for the earlier preparations. Examination by the viability test of the tissues which contained the drug revealed that there was some toxic action since, as may be seen from Figure 7, fibroblastic proliferation was not as luxuriant as in those instances when the bacteriostatic agent was absent. Furthermore, the toxicity appeared correlated with the concentration of sulfonamides, the 100 mg. per cent showing no growth after 7 days. On the other hand, with levels of 50 and 85 mg. per cent the sulfadiazine was not so deleterious as to prevent appreciable virus growth even at 35 days at room temperature since minimal inocula of virus in these preparations yielded dilution activities of $10^{-2.6}$ (see Table 1). The 21-day tests were more satisfactory and were active 10^{-4} . In view of the toxic action which the sulfadiazine appeared to exert on the tissues it has become customary to add the drug to the culture at the time of testing unknown specimens. In two series of tests which have been done since the present communication was completed, the *field cultures* have been used for recovery of virus from sputum and from contaminated mosquito suspensions.

In the case of sputum* a virus was recovered, but its place among the filterable agents has not been conclusively demonstrated beyond the fact that the agent almost certainly was correlated with the patients' pulmonary infection. However, it is of interest that following centrifugation in the Swedish angle the sputum could be tested in the *field cultures* containing 50 mg. per cent sulfadiazine without bacterial overgrowth taking place to such an extent that animal inoculation could not be carried out.

Preliminary investigations of contami-

FIGURE 7—Tissue from Serum Ultrafiltrate Containing 85 mg. Per cent Sulfadiazine Compound after 35 Days at Room Temperature in Two Cultures (Compare with Figures 1 and 2)

* Unpublished data—Sanders, Bullowa, and Alexander.

nated mosquito suspensions* (kindly provided by Dr. W. McD. Hammon) have demonstrated the ability of the *field cultures* to carry contaminated inocula without overgrowth of bacteria. Furthermore, in two other experiments whole untreated mosquitoes have been placed in the bacteriostatic environment of the sulfonamide-containing cultures. Although no virus appeared to be present, it was interesting to note that the heavy contamination, present in the whole mosquitoes became progressively lighter by serial passage in the field cultures until bacteria-free cultures were obtained.

How useful the cultures will be for detecting and recovering virus from specimens remains to be seen. Yet in view of previous work there is every reason to expect them to be satisfactory indicators of the presence of viruses capable of proliferating in the presence of embryonic chick tissue. Additional data based on the use of more highly differentiated tissue (e.g., embryonic

mouse brain) will be forthcoming in the future.

CONCLUSIONS

1. Small amounts of embryonic tissue in 2 ml. of serum ultrafiltrate have remained viable at least 35 days at room temperature ($25^{\circ}\text{C.} \pm 7^{\circ}$) for at least 4 weeks at 37°C. and 3 weeks at 4° to 6°C.

2. Numerous cultures can be made from one chick embryo and no manipulation of the cultures is necessary for the periods designated.

3. The addition of sulfadiazine mixtures have a slightly toxic effect on the tissues, but the drugs may be used as bacteriostatic agents so that contaminated specimens may be tested for virus content.

Philosophy and Future of Milk Control*

J. LLOYD BARRON, C.E., F.A.P.H.A.

*Director, Division of Sanitation, Nassau County Department of Health,
Mineola, N. Y.*

SANITARY milk regulation has developed slowly, haphazardly, and with little geographical uniformity. It began at points of densest population where adequate supply and distribution were major problems. Its most insistent stimulus has come from recurring epidemics and chronically high death rates among infants and children, supplemented by the economic demand for milk with keeping qualities outlasting the period between production and consumption. Being dependent on public health organization, milk control has necessarily been irregular and inefficient to the degree that local health agencies have lacked purpose and qualified personnel.

Because the future must grow out of the past, it is appropriate in discussing what may hereafter develop in milk control to review briefly the way in which we have arrived at the present stages of regulation and sanitation.

It was just fifty years ago that Nathan Straus began the free distribution of pasteurized milk on the lower east side of New York City, with results confirming his conviction that general pasteurization must become the safeguard of this essential children's food. Minnesota enacted a dairy inspection law in 1895. In 1896 the permit system

for milk dealers was initiated by New York City, although its legality was not finally established until 1905 when the Supreme Court ruled in favor of the city department of health; country milk inspection began in 1906; grading was instituted in 1912 when pasteurization was prescribed for Grade B milk. Not until 1926, however, was the sale of raw market milk in New York City completely prohibited and Grade C eliminated. The ultimate objective of a single grade of milk was achieved in 1940 with the adjustment of A and B requirements in both New York State and City to a set of standards applicable to all pasteurized market milk. A further significant step has now been taken by New York City in eliminating the sale of certified raw milk except on physician's prescription. A similar series of events came about in Chicago and they have been and are being duplicated in condensed form in many other urban areas.

A factor which has contributed tremendously to this transition of milk from dangerous irresponsibility to respectability has been the milk ordinance of the U. S. Public Health Service. The ordinance was first offered for general use in 1924, an interpretive code added in 1927, followed by frequent revisions and refinement of its subject matter.

The standard milk ordinance represents a synthesis of the experience and conclusions of the pioneers in milk

* Presented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

sanitation. These pioneers worked in an uncharted field with the untried tools of chemistry, bacteriology, mechanics, and government regulation. When they had demonstrated a large measure of success, their experience became the basis for a comprehensive ordinance and code designed to provide in any virgin area a complete regulatory instrument for milk sanitation.

The Public Health Service was in position to evolve such an instrument with a maximum of detachment from the actual problems of enforcement and the interplay of those forces which, in any given milk shed, profoundly influence the course of milk regulation. The Public Health Service was free to study the theory and practice of pasteurization experimentally and to incorporate all the refinements and to provide for all the conceivable contingencies that could affect the safety of milk.

The standard milk ordinance and its principle of grading were designed for adoption and enforcement in areas where the milk supply had not previously been subjected to effective sanitary control. Emphasis was necessarily placed upon farm inspection and upon those requirements tending to promote safety in raw milk. In actual experience, the goal of complete pasteurization was usually remote, and the immediate problems were to impose uniform regulations and to eliminate, as quickly as possible, inferior dairies and low grade milk. An interesting element of the ordinance has been the advisory relationship which the Public Health Service has attempted to maintain over the areas adopting it. This has involved a system for measuring enforcement and progress under the ordinance and a reporting to the Public Health Service at regular intervals for purposes of publishing compliance ratings.

The widespread use of the Public Health Service milk ordinance is indi-

cated by its adoption by 135 counties and 984 municipalities having a total population of 25,000,000 and located in 37 states and 1 territory (*Public Health Reports*, Vol. 58, p. 320, Feb. 19, 1943, and personal communication, A. W. Fuchs). On the basis of 90 per cent or more compliance with ordinance provisions, about 170 of these are currently listed as satisfactory, although not all of the communities are subjected to the qualifying surveys.

In the past several years, some conflict and controversy have arisen between the proponents of the standard milk ordinance and those who have developed and enforced other bodies of milk regulations. The Public Health Service would achieve uniformity in milk regulation by substituting the standard milk ordinance for all older systems and, in theory at least, bring all milk control areas under the advisory and coördinating influence of the federal agency.

Those who have been closely associated with the older but less definitive regulations have generally opposed their replacement by the standard milk ordinance for several reasons. First, the assumption on the part of the supporters of the standard ordinance that its particular form and completeness of detail somehow assure a higher quality of milk disregards the fact that the personnel and morale of the enforcing agency are the prime factors in achieving results.

Second, the emphasis upon farm inspection in the standard ordinance, while necessary in the early and educational phases of milk regulation, is not as productive of results as is deck inspection with its economy and directness of effort in the older milk sheds. The differences should be recognized between the milk shed subjected to initial regulation and starting with only a small percentage of clean herds, good barns, milk houses, réfrigeration, and so forth,

and the milk sheds where several generations of dairymen and milk handlers have become accustomed to regulation and accepted the routine technics and provided, as a matter of course, the physical facilities for clean milk production.

Third, there is a fundamental difference of opinion regarding the degree to which police power should be used by a regulatory agency. Until recent years, it has been generally accepted policy to restrict the use of police power to the attainment of minimum objectives of public safety. Consequently, necessity has largely dictated the content and extent of the older regulations in their slow evolution. On the other hand, the standard milk ordinance is a full-blown instrument which appears to go beyond the level of a reasonable degree of safety in milk. It stresses method and procedure rather than end results and, with respect to the process of pasteurization, sets up requirements of mechanical safeguards for every type of failure or interruption of routine which can be remotely anticipated. Is it desirable to burden both the plant operator and the inspector and to complicate plant equipment with precautionary devices and procedures which rarely, if ever, are required to function? Safety is relative rather than absolute, and a high degree of safety has been achieved by basic pasteurizing equipment and responsible operation. Should not our objective be a minimum rather than a maximum of regulation so long as it achieves the practical objective of eliminating pasteurized milk as a factor in communicable disease?

In the history of milk regulation, the city or local political subdivision has been the chief functioning agency. States have in the past largely ignored what might be considered an acute local problem. It is, therefore, only as the benefits of local sanitary control have been demonstrated that state agencies

have been forced to recognize their responsibilities in promoting official supervision wherever milk is commercially handled in quantity. In the absence of such state participation we have that anomalous situation wherein large cities are forced to maintain widespread country milk inspection services which operate to the benefit of satellite communities and lesser cities within the milk shed, without their sharing in the cost or the responsibility. To the extent that the lesser communities do carry on country milk inspection, there is duplication of effort and sometimes conflict and confusion. Yet these communities are not in position to make demands upon or to influence the course of sanitary control by the dominant local health agency.

Country inspection by a city is further unsatisfactory in that it is without police power at the point of inspection and the only punitive measure possible is exclusion of the dairy. Exclusion of a bad dairy frequently results in the sale of its milk in the local area where control may be negligible. Such milk, rejected for pasteurization, is certainly unfit for consumption as raw. The frequency of epidemics involving raw milk in rural areas is not unrelated to this form of inspection which has responsibility only to a limited and distant population.

The answer to this situation is, of course, the assumption by the state of dairy inspection and certification on behalf of all political subdivisions within the state. Only in this way can the quality of milk be improved for small towns and villages now unable to maintain even rudimentary milk control. The tax burden for this service would be equitably spread upon all the population served through a single state agency. This agency should be the state department of health. In a proper relationship between state and local health departments, the latter

could expect and demand efficient and responsible service in the sanitary control of distant milk sources, and the state could in turn require such local farm inspection on behalf of the statewide program as local personnel, resources, and circumstances would permit. Only in this way can local health authorities concentrate their major attention on processing and the condition of milk upon delivery. Only in this way can milk as a commodity be freed from present artificial restraints upon movement, and economics be effected through actual competitive marketing. Further, it is only in this way that milk going directly into dairy products such as butter and cheese can be subjected to the sanitary control it has so generally lacked for these uses.

Objection may be made to this proposal on the grounds that the local unit, vitally concerned with milk quality, would relinquish a responsibility to the state where it might be discharged with less severity and thoroughness. To this, the answer should be that sanitary control of milk will not be efficient or thorough, either on state or local levels, if adequate and technically qualified personnel are not employed. Given a well directed and staffed state organization, systematic and effective dairy inspection becomes a matter of professional responsibility, requiring only financial support and freedom from political interference.

In New York State, a legislative act requires all dairies outside and selling within the state to be inspected and approved by the State Health Department.

While the motive of this legislation was restrictive as to competition, and therefore questionable, it has resulted in a demonstration of the practicability of dairy inspection carried on at the state level and points the way to its logical extension to the sanitary control of all milk supplies used within the

state for whatever purpose and from whatever source.

In our contemplation of the future of milk control, we must recognize the fact that large volumes of milk daily move interstate. This movement has been largely within well defined milk sheds and restricted by the inspection limits of some health authority, supplemented in its control, perhaps, by a federal marketing agency. However, the war has suddenly disturbed this situation and caused new concentrations of populations at points remote from adequate milk sources. For example, to meet these changed conditions, milk is now being shipped from New York to Georgia and from Minnesota to Florida for pasteurization and fluid consumption. The disruption of milk sheds has forced a modification of milk regulations, including the formulation of the "Emergency Sanitation Standards for Raw Milk for Pasteurization" for those areas receiving milk from non-standard ordinance jurisdictions.

Prior to this modification in December, 1942, a situation had developed in which the universal adoption of the standard milk ordinance was being urged as in the national interest to make possible the movement of milk to points of increased civilian and military use. At the same time, surveys were being made to determine the acceptability, under standard ordinance provisions, of milk from areas such as the New York City milk shed. These surveys, by the ratings obtained, apparently determined that milk daily consumed in New York City was unsatisfactory and, therefore, by inference, unsafe to be received by a Georgia pasteurizing plant. Such findings were derived chiefly from differences in requirements relating to dairy farm equipment and inspection procedures rather than from any comparison or determination of milk qualities. Because such a position was untenable, certain stand-

ard ordinance areas have since modified their requirements to the extent of adopting the emergency sanitation standards, previously referred to, as applied to milk imported for pasteurization.

There has long been a cry for greater uniformity in milk regulations. Uniformity can be achieved only as all authorities are willing to examine the content of regulations in the light of reasonable objectives of safety and in the broad perspective of interstate traffic in milk unhindered by artificial barriers. The present war has forced a long step in this direction and the future may be revealed somewhat by projecting these trends.

One of the most persistent barriers to uniformity is the unwillingness of one health jurisdiction to recognize enough good in the milk control activities of another to warrant acceptance of its milk. This attitude, combined with the provincial opposition to distant commodities competing with home products, supports the arbitrary restraints now impeding the movement of milk between cities and between states. These restraints admittedly developed when effective milk control was the exception and were necessary to exclude inferior milk from quality markets. But we are coming to a time when milk control in the larger market areas will be found increasingly effective. How then may one community be assured of the antecedents of a surplus or a regular supply of milk from another producing area without maintaining a costly and burdensome inspection service?

The first requirement, to return to a previous thesis, is the state-wide inspection and certification of dairies by a state authority, preferably the state health department. Within the state, certainly, regulations affecting market milk should be uniform, and the inspecting agency should be an acceptable

supervisor, coördinator, and clearing-house for milk sources under either local or direct state inspection. The state agency should have both the machinery and the fortitude either to reject the milk from substandard local areas or to supplant local by state inspection until conformity is established.

If this is a rational and desirable arrangement within a state, what of the interstate relationship? States are no more willing than municipalities to accept unverified representations of milk quality. The need, therefore, is for a certifying agency of standing and technical competence to function on a national scale. For this rôle, the U. S. Public Health Service is the obvious choice.

The present system of certification of shellfish has demonstrated the efficacy of such an arrangement. The Public Health Service acts in a supervisory capacity in determining whether the shellfish as produced in a particular state conform to an accepted standard. Such a state reports to the Service those dealers and shippers who conform to such state enforced regulations. The Public Health Service, in turn, transmits such lists to other states and municipalities certifying that they are satisfactory. If the standards or enforcement within a state are unsatisfactory, the Public Health Service may (and does) withhold certification of all its shellfish products. While this system may not prohibit the interstate movement of shellfish from such a state, responsible health departments generally by local regulation prohibit the sale of shellfish not so certified, thus making the system work.

For such a procedure to function for milk, it is necessary that at least some states establish dairy inspection at the state level. The procedures for this purpose must have substantial uniformity as between states and must be acceptable to the Public Health Service.

The achievement of such uniformity and agreement will first require, on the part of the Public Health Service and many state and local health departments, a considerable exercise of statesmanship and a vision of the greater good. Arbitrary attitudes and extremes of perfectionism, conservatism, and local pride will have to be sacrificed to some extent in such a coöperative undertaking. The real objective is, of course, not mere similarity in the wording of milk codes, but substantial conformity to standards of personnel performance, coverage of milk sources, and maintenance of actual milk quality.

At the present time a committee of the International Association of Milk Sanitarians is assigned to make a sur-

vey of milk regulations and the extent to which they lack uniformity. Public health and technical organizations concerned with milk sanitation should foster every tendency toward widespread distribution of milk control on a basis of unhindered reciprocity between states and cities so that public health factors will no longer support artificial barriers to the movement of milk to market.

We must recognize that a time is coming when milk will be transported half way across the continent by tank plane, and milk inspectors will hop from dairy farm to receiving station by helicopter. Let us speed the day when milk will no longer be criminally suspect merely because it has been transported from one place to another.

DISCUSSION

A. W. FUCHS, C.E.

Sanitary Engineer Director, U. S. Public Health Service, Washington, D. C.

THIS is an excellent paper and an interesting subject for discussion. The central theme is the need for greater uniformity in milk sanitation standards to avoid duplication of inspection and to promote the free flow of milk from one milk shed to another both interstate and intrastate.

Only those who wish to erect a Chinese wall around their milk shed to shut out competitive milk supplies will quarrel with this theme. Members of the industry supplying different markets are confronted with a real problem arising from the multiplicity of milk laws and regulations in effect in different states and even in different cities within the same state. Milk control agencies are burdened with the expense of overlapping inspections. Certainly the public health must be safeguarded, but this can be accomplished by the adoption of uniform standards which

would make possible the mutual acceptance by one area of inspection reports made by another.

For many years the Public Health Service has directed its efforts at promoting an adequate and uniform milk sanitation program and organization in each state health department to promote and supervise uniform local control. It has recommended a model milk ordinance for voluntary state and local adoption. This ordinance is now in effect in 135 counties and 984 municipalities ranging in size from under 1,000 to 3,500,000 with a total population of approximately 25,000,000. These areas are located in 37 states and Alaska, i.e., in all except California and the 10 northeastern states. In addition, 14 states have adopted it in whole or in part as state regulations, and 6 more have enacted state laws incorporating its grade definitions. In 1931 the

model ordinance received the approval of the Bureau of Dairy Industry of the U. S. Department of Agriculture. It has been recommended repeatedly for general adoption by the Committee on Milk of the Conference of State and Provincial Health Authorities. In recent years it has been used as a basis for the federal specifications for fresh milk, applicable to all federal departments and agencies, including purchases for the Army and Navy. Its standards are also incorporated in the Interstate Quarantine Regulations to govern milk served on interstate common carriers.

As the Public Health Service milk ordinance is in effect in a far greater number of communities and over an overwhelmingly wider area than any other set of standards, it is logically the one that should be supported by everyone who realizes the need for uniform regulations. The ordinance has passed through the crucible of many revisions suggested by research and experience. There is no reason why it could not be further improved, if necessary, along such lines as may be acceptable both to areas now using it and to those which might use it.

The paper under discussion lists several reasons why certain areas are opposed to the recommended ordinance. Is it not significant that objections to this program come almost entirely from persons who have had no actual experience with it, rather than from those who operate under it and are thus in position to appraise it properly? That is because some of the objections are based on misconceptions regarding its contents and operation. It may therefore be profitable to examine some of the author's statements.

1. It is alleged that the recommended ordinance with its grading provisions is designed for areas without previous effective milk control. This indictment is not in accord with the evidence. Many areas with long ex-

perience under other ordinances or regulations also employ a grading system. In 1936, 86 per cent of the municipalities in New England and the Middle Atlantic States which returned our questionnaire reported the use of grades.¹ True, in some cases the grades are designated by such terms as "select," "inspected," "guaranteed," "special," "market," and "family," rather than by letters; but it is grading, nevertheless. Furthermore, many cities with previous milk control experience are now using the Public Health Service program; among the larger ones are Atlanta, Chattanooga, Charlotte, Chicago, Dallas, Fort Worth, Houston, Indianapolis, Jacksonville, Kansas City (Kans.), Kansas City (Mo.), Knoxville, Louisville, Memphis, Miami, Oklahoma City, Portland (Ore.), Richmond, St. Louis, Salt Lake City, San Antonio, Seattle, Tacoma, and Tulsa.

Incidentally, two aspects of the grading provisions of this ordinance are frequently misunderstood and deserve clarification. First, there is the misconception that all of the grades defined in the ordinance are actually sold in all areas operating under it. This is not the case, since section 8 is flexible and leaves to the adopting community the decision as to which grades shall be prohibited. Chicago, for example, permits the sale of only one grade—Grade A pasteurized. Second, there exists the impression that Grade A as defined in this ordinance is a supergrade commanding a high price differential. This may be true in certain areas operating under other regulations, but it is diametrically opposed to the philosophy of the Public Health Service ordinance. Under the latter, Grade A is the normal grade available to everyone at normal prices; the lower grades are usually sold in the larger cities only during periods when a Grade A supply has been temporarily degraded for failure to comply with the Grade A standards.

2. It is alleged that the completeness of detail of the ordinance is a burden both to the plant operator and the inspector, that it is more important to have qualified inspectors, and that our objective should be a minimum rather than a maximum of regulation. This complaint undoubtedly represents a failure to distinguish between the ordinance and the code. Only the ordinance portion is adopted locally, and this occupies less than 17 pages of *Public Health Bulletin* 220—a briefer instrument than many other city milk ordinances and state regulations. The remainder of the 160 page *Bulletin* consists of the explanatory code, which gives the public health reason for each requirement and details of satisfactory compliance. It is the very detailed nature of the code, indeed, that makes it so valuable to those who use it, for it promotes uniform enforcement, avoids unreasonably stringent interpretations on the part of some inspectors and too lenient ones by others, and reduces disagreements with the industry. The code material on pasteurization incorporates the results of many researches and provides reference material to guide the inspector on a highly technical subject. It has resulted in greater uniformity and higher standards for equipment manufacturers. It has served as a textbook in many colleges, and has been widely termed the "Milk Inspector's Bible."

The need for qualified inspectors has long been recognized and supported by the Public Health Service in many ways. That, however, is irrelevant to the immediate question. The same inspector will be better qualified if he has available a definite detailed technical guide than if he relies on unwritten regulations or his own whims. To allege that the detailed explanations in the code are a burden on the plant operator and the inspector is equivalent to saying that newspapers are a burden on the public,

or that a textbook is a burden on the student, or that the *American Journal of Public Health* is a burden on our members. On the contrary, far from being a burden, the pasteurization standards of the code have been followed by some of the best plants and by many inspectors outside of Public Health Service ordinance areas.

3. The next allegation made in the paper is that the recommended ordinance places too much emphasis on farm inspection and too little on less expensive deck inspection, that it stresses method and procedure rather than end results. This question merits more detailed consideration than the time limitation will permit.

Farm inspection is necessary not only to insure proper equipment and to detect insanitary technic, but, more important still, to educate the producer in correct methods. A good inspector is primarily a good educator, and the educational approach is more effective in the long run than the policeman attitude. It is reasonable to suppose that the higher the inspection frequency the better the results. One milk inspector observed that bacterial counts rose during a period when he was without an assistant and when the frequency of farm inspection was therefore reduced. However, an inspection frequency above the optimum fails to achieve results commensurate with the cost. Our 1936 questionnaire survey revealed that producing farms throughout the country were officially inspected an average of 7.7 times per year, and that 30 per cent of the municipalities were inspecting them monthly or oftener.² The Public Health Service ordinance requires a minimum of 2 inspections per year. By contrast with average practice, this frequency cannot be considered excessive by any stretch of the imagination. Indeed, the ordinance has been criticised for not specifying a greater frequency.

Laboratory and deck examinations are valuable, but they cannot be relied upon as the sole means of judging milk quality. A milk supply with a low bacterial count may be secured from farms with infected cows, insanitary privies, germ-laden flies, improperly sterilized milk utensils, unprotected wells, and even moderately unclean milk handling under low temperature conditions. It may be argued that pasteurization renders such milk safe. But pasteurization is subject to human frailty, slips occasionally occur, heat-stabile enterotoxins may not be completely destroyed, and disease outbreaks from improperly pasteurized milk are reported none too rarely. As long as there are no routine tests capable of detecting all pathogens in milk within the brief period between production and distribution, it is impracticable to determine with certainty the safety of a supply solely by testing the milk. Samples for such tests as are available, including bacterial and phosphatase, cannot be taken with sufficient frequency and in sufficient volume to represent adequately the entire supply. There is as yet no universal agreement among laboratory men on such a fundamental question as the most suitable bacterial tests among the plate count, the direct microscopic count, and the various reduction tests. In addition, our recent surveys of milk laboratories throughout the country indicate that nearly all milk laboratories depart to a greater or less degree from *Standard Methods* and that many of the results are consequently unreliable. Finally, it should be remembered that safety is not the only criterion of quality. Milk must also possess a maximum of palatability if greater and more widespread consumption is to be promoted in the interest of improved nutrition. Palatability is largely the result of clean methods of handling on the farm.

What conclusion can we draw? It

seems inescapable that neither inspection alone nor laboratory methods alone can be relied upon for proper control of milk production. The milk sanitarian would be unwise if he refused to utilize all the tools at his disposal. The Public Health Service ordinance stipulates at least 2 farm inspections and 8 bacterial and temperature samples from each producer per year. It is conceivable that this program might be improved by requiring, in addition, a minimum frequency of deck examinations at the receiving platform, provided that deck examinations are proved to be feasible for small plants in small milk sheds. It is hardly likely, however, that a single farm inspection per year would be acceptable during peacetime to areas outside the northeastern states. The argument on costs is not convincing: in 1936 the average expenditure for official local milk control in the 3 southern geographic divisions was approximately 6.2 cents per capita as compared with 6.8 cents in the 2 northeastern divisions,³ and if industry costs were added the difference would be considerably greater. Perhaps the future will reveal what combination of inspection, sampling, and deck examination frequencies will produce the best results at the least cost.

Having discussed the objections listed in the paper to the Public Health Service milk ordinance, let us now return to the author's main thesis, namely, the need for greater uniformity in milk regulations. To avoid duplication of effort and to promote the free flow of milk, he proposes that the state should assume dairy inspection and certification on behalf of all political subdivisions within the state. Theoretically, state-wide control should be more efficient and more economical than local control. That it has not been generally adopted would indicate a prevailing preference for local control. Adequate state-wide control would re-

quire so large a staff that the program would be in constant jeopardy of being disrupted or crippled through failure of continued appropriations or through constant pressure for the appointment of political inspectors. With local control, on the other hand, these dangers affect individual cities only, not the entire state. This need be no cause for discouragement, however. Experience indicates that state-wide control is not necessary to achieve uniformity, since uniformity has been attained to a considerable extent by the local adoption and enforcement of a uniform ordinance under the supervisory guidance and leadership of a limited state staff. There are now quite a number of states in which practically every municipality has voluntarily adopted the Public Health Service ordinance.

Nor would state-wide control solve the problem of interstate barriers even if all states adopted the same regulations. We need not only uniform standards but also uniform interpretation and enforcement. The Public Health Service recognized long ago that the mere adoption of uniform legislation throughout the country does not of itself assure uniformity of enforcement.

For promoting excellent and uniform enforcement the Public Health Service developed a milk shed rating method for the periodic measurement of the control work of municipalities by the state milk control authorities. This is described in *Reprint No. 1970* from the *Public Health Reports*. Many states have been making such ratings for years and submitting them for the purpose of publishing periodically in *Public Health Reports* a list of the communities achieving high ratings. The publication of this list has greatly stimulated good enforcement and has acquainted cities experiencing a milk shortage with areas from which satisfactory supplies can be obtained. Occasional standardization ratings by the Public Health Service reveal whether the rating methods of the shipping state are acceptable. By this system a receiving community is afforded all necessary and legitimate public health protection of its distant sources of supply. It is offered as a means for overcoming existing trade barriers and duplication of inspection.

Engineering Problems in the Use of Glycol Vapors for Air Sterilization^{*†}

BURGESS H. JENNINGS AND EDWARD BIGG, M.D.

Professor and Chairman of Department of Mechanical Engineering, Northwestern Technological Institute; and Instructor in Medicine, Northwestern University Medical School, Evanston, Ill.

NONE of the various methods which has been proposed for reducing the incidence of respiratory diseases has ever been found completely effective. Immunizing sera and vaccines have been of great value but the need of further measures is apparent. From the time of Lister's early experiment with phenol sprays, many investigators have attempted to bring about reduction in the bacterial content of air by chemical agents. Until the last few years, however, satisfactory materials to accomplish this have not been available. The ideal substance is one which would be non-toxic, odorless, imperceptible to the occupants, effective in very small concentrations, easy to distribute, and reasonable in cost. Certain of the glycols, i.e., propylene and triethylene appear to fulfil most of these requirements. They are non-toxic, essentially odorless, available, reasonable in cost, and their bactericidal action is dramatic in its effectiveness.¹ Until the low toxicity of these substances was established, large scale investigation could not be carried forward. The work of Robertson² and his coworkers has demonstrated that triethylene glycol

(TEG) and propylene glycol (PG) are non-toxic, even in much greater concentrations than those which are required for effective bactericidal action for air sterilization.

Numerous tests have given evidence that effective killing of air-borne bacteria and viruses is accomplished by either TEG or PG vapor.^{3, 4} Since practically all prior work had been done in small test chambers, it was evident that before full utilization of these glycols material could be possible and controlled studies of their effect in the reduction of cross-infections could be carried out, experimentation in full-scale chambers and with actual living groups had to be made.

We have shown that in our experimental room (10,000 cu. ft.) concentration of TEG ranging from 0.003 to 0.005 milligrams per liter (0.0013 to 0.0022 grains per cu. ft.) bring about instantaneous killing of bacteria sprayed into the space (Figure 1). Similar results are obtained with concentrations of 0.1 to 0.2 mg. per liter (0.044 to 0.088 gr. per cu. ft.) using PG.⁵ A humidity of 35-45 per cent should be present to insure optimum effectiveness. Our tests have shown that bactericidal action occurs exactly as had been demonstrated in the previous small chamber experiments.

The next phase of our study was concerned with the development of the

^{*} Presented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

[†] The work described was done under contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Northwestern University.

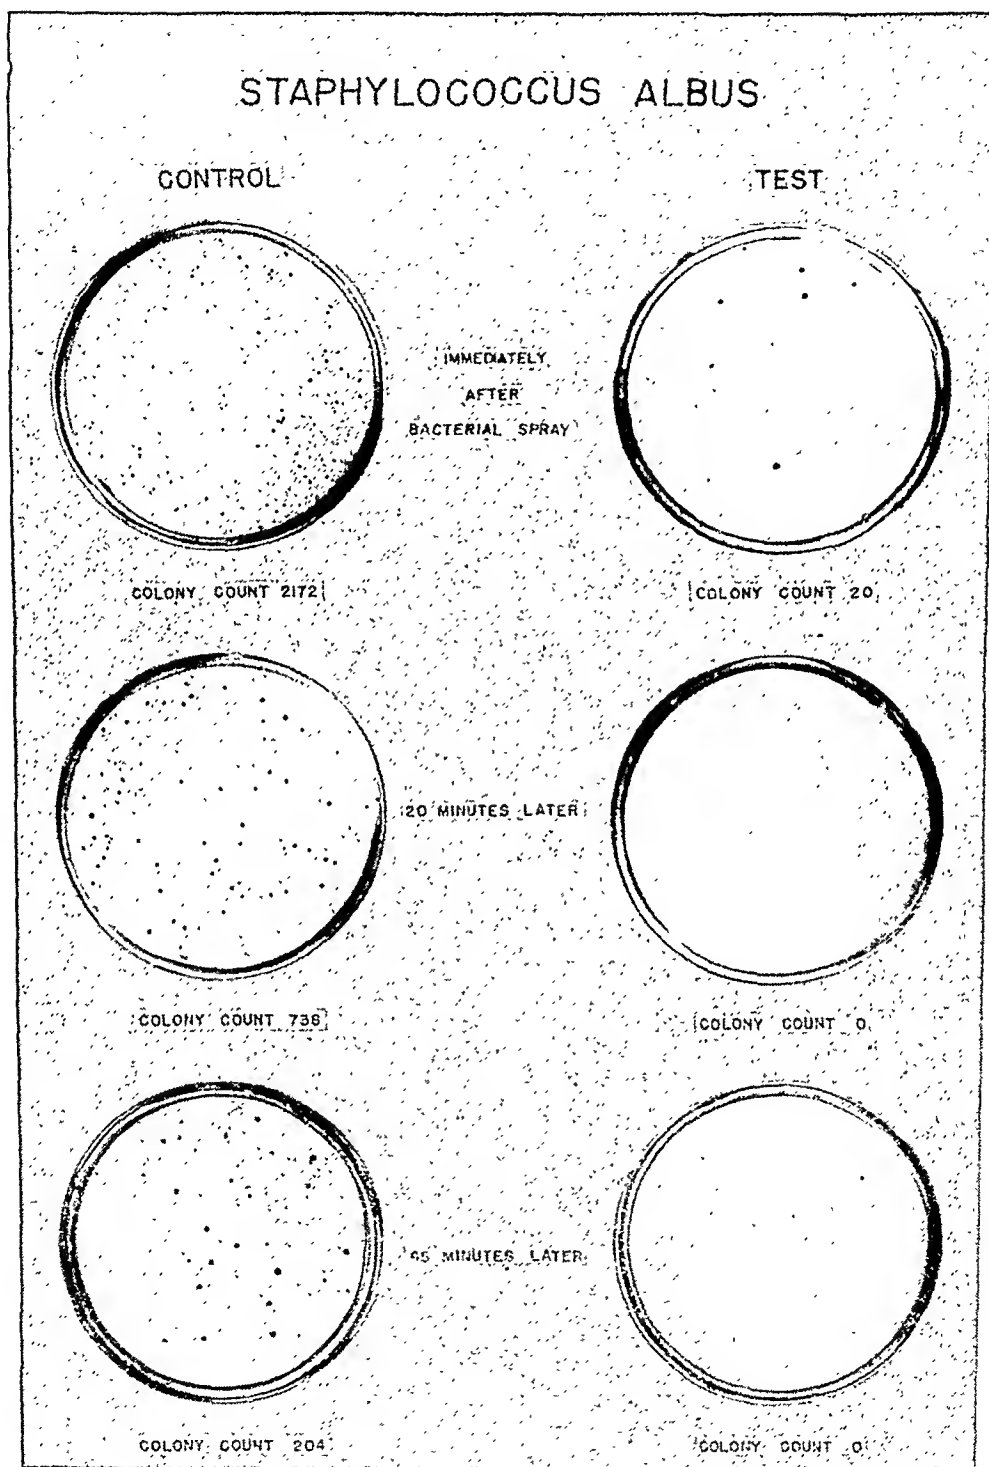

FIGURE 1—Bacterial plates showing the number of organisms per cu. ft. recovered after spraying an equal quantity of a standardized suspension of *Staphylococcus albus*. The room humidities were 45 per cent and the triethylene glycol concentration in the test was 0.004 mg. per liter.

FIGURE 2—Test room showing apparatus for the introduction of bacteria and for air samples of glycol and organisms

engineering data required for the application of the glycols as bactericidal agents for occupied spaces.

TEST LOCATION

These tests were started at the Technological Institute, Northwestern University, in July, 1942. Use in particular was made of the large air conditioned test room of the Institute (Figure 2). This room is 38 ft. long, 17 ft. wide and 16 ft. high, and has an approximate volume of 10,000 cu. ft. It was insulated and extremely tight in regard to air infiltration or exfiltration. Large refrigerator type doors were used for entry and over each of the windows. This made it possible to observe the action of the glycol supply without having to consider large quantities of uncon-

trolled air. This room was connected to a complete air conditioning system, such that its temperature could be varied from -20° F. to $+140^{\circ}$ F., and its humidity-controlled. In the tests up to the present, it has not been found necessary to operate the air conditioning system.

SIGNIFICANT PHYSICAL PROPERTIES OF PROPYLENE AND TRIETHYLENE GLYCOL

Careful studies were made in order to ascertain the concentration of propylene glycol or triethylene glycol in equilibrium with air of a given humidity. These data are fundamental to the entire problem of the use of glycol vapor in air spaces. From such observations one may determine how great

or small a quantity of glycol and water vapor may be held in air at given temperatures and humidities, at what point condensation would be expected to occur, and at what point perceptible fog appears. Furthermore, as will later be shown, the final development of a practical "air-glycol atomizing

humidities it will probably be impossible to maintain a consistently high glycol concentration in its vapor phase.

Before tests in living spaces could be attempted, the inflammability characteristics of propylene and triethylene glycol were studied intensively.⁶ Our observations, in brief, showed that:

FIGURE 3—Curve showing quantities of propylene glycol and water in equilibrium at a temperature of 70.5° F.

scrubber" will depend upon a knowledge of these values.

As shown in Figure 3, preliminary data have been obtained. These data are being restudied, using both PG and TEG, by more precise technics so that more accurate values will be available. It may be seen, however, that at an arbitrary temperature, i.e., 70.5° F., the vaporization of water-propylene glycol solutions results in constant concentrations of water and glycol vapor in the air. Thus with high relative

1. The vapor-phase concentrations required for air sterilization were completely free of any fire hazard.

2. The presence of water in combination with glycol greatly reduced its combustibility. This was particularly significant, since samples of condensed material from surfaces as cold as -20° F. never contained more than 20 per cent glycol. It is impossible to ignite such solutions even with prolonged application of heat.

3. The introduction of small quantities of water with glycol renders large storage tanks relatively inactive as far as inflammability is concerned.

BEHAVIOR OF GLYCOL VAPOR IN TEST ROOM

Two effective means of generation of glycol vapor were developed and both were used in our experimental room. The first employed an atomizing principle, and the second generated the vapor by heating. Both methods showed that glycol vapor when delivered into the space had little or no tendency to stratify, it diffused readily through the space and, if air exchanges to outside spaces were kept to a minimum, the concentration decreased at a slow rate. There was evidence of a slight amount of absorption on room surfaces.

Since relative humidities of 35 to 45 per cent are desirable, condensation of water and glycol vapor takes place on cold surfaces, such as windows or poorly insulated walls in cold weather. The necessity for the maintenance of 35 to 45 per cent humidity also means that water vapor must be introduced into heated spaces during periods of low humidity, such as exist in winter. It has been found that the addition of water with introduced glycol can easily be made.

APPARATUS FOR GLYCOL GENERATION

As mentioned before, two means of glycol vapor generation were developed. The first utilized atomization of glycol water solutions of automatically controlled concentrations. In this method the solution is sprayed into a large mixing chamber containing a system of baffles to eliminate droplets. Equilibrium takes place between the air passing through the chamber and the sprayed solution. Complete and final data on the operation of this device have not as yet been obtained. However, the glycol water solution produces a definite concentration of glycol and water vapor in the air issuing from the outlet. It may also be seen that if the room air is recirculated through the

mixing chamber it will pick up only the difference between its glycol content and the maximum content. The maximum possible glycol content depends on air temperature and on the glycol concentration of the atomized solution. When final details and refinements have been worked out, it will be possible to produce a vapor of constant concentration controlled by the amount and temperature of the air being passed through the atomized mixture and by the concentration of the liquid being sprayed. It should be observed that by fixing the solution concentration, the glycol content in air can never exceed a predetermined maximum at any room temperature. Vaporization of some of the atomized water also contributes to raising the space humidity. This method will probably be most applicable in the case of existing air conditioning systems with duct work in place.

The second type of apparatus developed was one in which water glycol solutions were boiled at constant temperatures. The concentration of the vapor emitted is dependent upon the glycol water concentration of the solution and the rate of production of vapor depends upon the rate of boiling, i.e., rate of heat input. Both the boiling temperature and the concentration in the reservoir can be automatically controlled. Thus, just as in the atomizing (scrubber) device, one can introduce controlled quantities of water vapor in conjunction with controlled quantities of glycol. This apparatus is small, compact, and easily portable so that it offers certain advantages over the first method.

SUGGESTED INSTALLATIONS

Although natural air and convection currents in a space tend to distribute the vapor to a certain degree, it is felt that some means of air agitation is very desirable. In ordinary living spaces of moderate capacity fairly uniform dis-

tribution can be obtained by the use of oscillating fans.

When larger installations are to be made, particularly in large gathering places, such as auditoriums and hospital wards, the use of a duct system plus a blower-type fan seems desirable. In the typical layout of Figure 4 a duct is located near the ceiling and at the center of the room, fitted with outlet grilles to allow uniform escape of glycol laden air. The volume of air to be moved is dependent upon the size of the space and the number of individuals present.

fresh and recirculated air should be accurately controlled by means of dampers.

The ultimate answer to the rate of introduction of glycol vapor and water vapor will, of course, be dependent upon the rate of infiltration and exfiltration of air from outside or adjacent spaces.

MEANS OF DETECTION OF GLYCOL VAPOR

The final apparatus for practical application depends upon the development of a device which will readily detect adequate concentrations of glycol vapor in the treated space. This should

FIGURE 4—Diagrammatic illustration of suggested duct layout for glycol vapor distribution

The two types of glycol generators are shown, the atomizing (scrubber) device being indicated by broken lines. It may be seen that allowance is made for introduction of outside (fresh) air. Thus, all the air to be introduced must pass through or by the incoming glycol vapor and be mixed with it so that only "glycolized air" issues from the outlets in the duct. For best operation the room should be sealed as completely as possible and the relative quantities of

operate in a manner similar to a thermostat, turning the glycol generator off or on in response to variations of glycol concentration in the room. Preliminary studies on several types of such devices are being carried out but none are as yet completely satisfactory. Thus, for our studies in living groups manual operation of the generator will be necessary.

DISCUSSION AND CONCLUSIONS

The data already obtained indicate

that the results secured in the laboratory should be equally applicable in occupied spaces. As yet no conclusions can be drawn as to whether bactericidal concentrations of glycol in the air of living spaces will significantly affect the incidence of cross-infections of air-borne disease. Other factors such as the amount of dust in the air, the proximity of one person to another and the virulence of the infecting agent, all play a rôle in cross-infection. However, one would expect that the presence of a "bactericidal curtain" surrounding each individual would reduce the possibility of that individual transmitting or receiving virulent organisms. Final conclusions must depend upon adequate

and well controlled field trials which are now being organized.

Favorable and Adverse Developments in the School Environment*

ABEL WOLMAN, DR.ENG., F.A.P.H.A., ALFRED H. FLETCHER,
F.A.P.H.A., AND WILMER H. SCHULZE, PHAR.D.

Professor of Sanitary Engineering, The Johns Hopkins University; Associate in Sanitary Engineering, The Johns Hopkins University; and Director, Sanitary Section, Baltimore City Health Department, Baltimore, Md.

IN a recent bulletin issued by the Committee on Administrative Practice of the American Public Health Association (*Health Practice Indices*) a series of charts are shown indicating the range of accomplishments in various fields of community health service. The material had its origin in the *Evaluation Schedules* submitted for the National Health Honor Roll for the years 1941 and 1942. The health practices summarized in the pamphlet may be assumed to be reasonably indicative of the progress attained in the different health services of some of the more progressive communities.

It is disconcerting, therefore, to note that, of the rural school children served with satisfactory water supplies, the median group still shows a deficiency of almost 20 per cent. As the pamphlet itself indicates "There are all too many areas where rural school children are forced to use unsatisfactory water supplies with their attendant potentialities as sources of water-borne illnesses."

For over one-quarter of the total number of communities surveyed satisfactory water supplies are unavailable

to rural school children to the extent of from 35 to 70 per cent of the children involved.

In the case of satisfactory means of excreta disposal, the situation is somewhat better, although in the median group of rural school children approximately 10 per cent are still unprovided with satisfactory excreta disposal facilities. In one-quarter of all of the communities analyzed, unsatisfactory means of excreta disposal are provided for anywhere from 25 to 80 per cent of the rural school children involved.

This none too flattering picture might be excused by some on the score that the situation is much better in the case of urban communities. Unfortunately such data as are at hand do not confirm this optimistic hope. In one community of over a million people, for example, approximately 10 per cent of the school children still have substandard sanitary facilities which would not be acceptable on any appraisal sheet. There is reason to believe that the physical environment of schools, both in rural and urban areas, is typical of the few instances here presented.

We need not blame the war effort for any major adverse developments in the school environment, except in so far as the war has intensified or stressed the obvious deficiencies and has been responsible, of course, for deferring at least some important correctives. Bear-

* Presented at a Joint Session of the American School Health Association and the Food and Nutrition and the School Health Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

ing this fact in mind, therefore, it is important to view the school environment as one which required attention over a long series of peace years rather than one which the contingencies of war have created. A simple explanation of these deficiencies of physical facilities of various schools, both rural and urban, resides in the fact that those interested in the health of children have moved rapidly toward the personal hygiene activities which promise and accomplish so much in lifting the level of the health of the school child. Unfortunately, these efforts have too frequently been founded upon defective underpinning of an environmental type. In other words, advances in medicine and in application of the results of medical research have been so rapid that the purely physical aspects of the school received less attention than 25 years ago, except perhaps in the direction of architectural aesthetics. Corresponding emphases on sanitary control of the school structures were lacking. These lapses are particularly unfortunate since the schoolhouse, from the lowest to the most lavish structure, should be the demonstration center for the education of children in the primary tenets of public health practice.

The best use of the school and its environs for the protection and permanent education of the child still lies in providing therein, not the more expensive, but the most adequate sanitary features which modern technology can provide. This is only loosely accomplished in a community where for many years one of the best places to demonstrate the most insanitary type of drinking fountain was in the most recently constructed public school, where school superintendent, architect, health commissioner, public health nurse, and sanitary engineer apparently were never introduced to each other.

Some people have facetiously referred to many of the newest public schools

as the concealed museums of unused air conditioning equipment. Here, too, the art of the salesman has outstripped the efficiency of intercommunications between school and health authorities. No inventory has ever been made of the amount of money invested in air conditioning equipment which has never performed a single revolution in fact since the date of its installation. That there are such, even a modest observer of schoolhouses could disclose.

The protection of the school environment, therefore, in so far as the sanitary engineer is concerned, has shown violent fluctuations from the provision of little or nothing to that which was too expensive and at times unnecessary.

The war has merely stressed these deficiencies and has piled them up. The war is not responsible, however, for the fact that in many expensive as well as inexpensive structures for school children natural and artificial light is poor; that in some vocational schools the conditions in the automobile repair shops are inferior to those which would be permitted in a commercial establishment for the same purpose; that in too many schools for colored children the toilets are dilapidated, lice and fleas infest the school, and the waste from drinking fountains and sinks finds its way comfortably to the nearest street surfaces; that in many of the most modern urban school systems in the country neither towels nor soap are provided for the school children to wash their hands after using toilet facilities, even though health department posters, gracefully designed to instruct the children in these habits, are prominently posted in the various toilets and washrooms.

It did not take a war in 1939 to disclose that hand-washing facilities were virtually absent in the school system of a number of large cities because the cost was considered by the school board to be prohibitive.

In other major cities of the United States, as late as June, 1939, schools for colored children were provided with outside privies, with no seat covers, with the pits not fly tight, and sufficiently odoriferous to be reminiscent of the textbooks of 1900.

It was not war which caused illness, in a large number of students, from fumes and gases in one of our most distinguished school laboratories because of the lack of adequate artificial ventilation, generally demanded under state regulations for industries. Nor was it war that made the classic location of illegal cross-connections in one of the most important high schools of a large city.

These examples are culled from the reports of various school surveys which have or have not found their way into the literature. They are impressive in demonstrating the conviction that long before World War II we had the elements of a major public health war in the field of school environment, in which the antagonists were within the departments of education and of health. This does not mean that equally excellent examples cannot be given of accomplishments and of coöperative effort between the departments of education and of health. There are many such, but the examples of the absence of such positive coöperative effort are still too many to be comforting to either the educator or to the health officer. Since these situations have become intensified because of war and because they will confront all of us in increasing degree as soon as peace is declared, the remainder of this paper will be devoted to outlining some of the elementary features of school environment, the control of which the members of the American Public Health Association may profitably take to heart. Most of these details are probably familiar to all of you. Perhaps they are so familiar that it is reasonable to ignore them even in

the installations. In rehearsing them for you some renewed interest may be generated in applying those sanitary standards and practices to the future which have been in the textbooks for many years in the past.

Much of our lifetime is spent in the home, the school, and the work place. Witness the family as they break up after breakfast for the day's work. The father leaves for the office or factory environment, the child for school, and the mother remains in the home. Many of the same fundamental considerations of sanitation apply to each of these environments. In *Preventive Medicine in Modern Practice* (edited by the New York Academy of Medicine) it is suggested that it would be well for experts in the hygiene of housing to participate always in the planning of new schools. It is easy to see how the problems of illumination, ventilation, heating, water supply, sewage disposal, fire hazards, and general housekeeping require the same fundamental engineering considerations, whether applied to the environment of 15,000,000 school children of the country or to the environment of the 50, or 60,000,000 workers.

Of course for a comparatively small percentage of workers exposed to special hazards specific to some manufacturing, mining, and mechanical industrial plants, there are special industrial hygiene problems in the control of dusts, fumes, mists, and gases, and in protection against accidents.

The school environment is planned by architects and engineers and is operated and maintained by the school custodian under the general supervision of principals. To the extent that the architect, custodian, and principal understand and appreciate the requirements of a healthful environment and to that extent only, will the new schools and the major alterations to existing schools be designed and constructed to

promote good and prevent ill health. Improvements and maintenance of existing schools are likewise planned by superintendents, business managers, and other officials of the boards of education. It is important that the school environment be planned to complement the hygiene program of the school and the health department. The problem is both medical and engineering and, where these services are available and interested, the health department can play a very useful and effective part in furnishing understanding and appreciation by translating health objectives into designs and specifications.

The problem of influencing the school board and superintendent is not unlike that of influencing other departments of government in order to accomplish needed improvements. The taxable wealth of the community, the political situation, the progressiveness of the community, and the personalities involved are basic considerations influencing the decision how best to handle the problem.

When Memphis, for example, began to give some thought to a program of school sanitation a few years ago it was found on inquiry that a rather complete course in hygiene had been prepared jointly by a committee of teachers and nurses. Sanitation was not referred to in any way, and the activities of the Bureau of Sanitation were not mentioned. The sanitary engineer had not indicated by any planned activity in the schools any interest in the school environment as a whole beyond that of restaurant inspection and of checking connections to public water and sewerage systems. A first move was to survey all of the schools of the city. A form was developed for reviewing each schoolroom and for scoring each school building from the standpoint of design, construction, and equipment, as part I, and maintenance, operation, and educational effort, as part II. Because of the

variation in the illumination found in individual rooms and the many factors involved in providing satisfactory illumination, it was necessary to record these items for each room on a separate sheet.

As the survey progressed the superintendent of schools was acquainted with the results and he became much interested in the information which was being developed. A summary of scores for the first 23 schools surveyed was prepared and submitted. This was the health department's estimate of how the various schools compared with each other and where improvements were needed. This estimate could be compared with their own evaluations. A program of improvements was made up each year, and money was set aside for them in the budget. The superintendent asked that the business manager of the board be kept informed of the progress made and that all reports and plans be filed in his office. The business manager expressed considerable interest, and asked that specifications for drinking fountains to meet the health department's approval be drawn to guide him in the purchase of about 1,000 nozzles for replacements for the next year. Soon a request came from the architect that tentative plans for a new school be looked over for criticism and recommendations before final plans were drawn. This was done, and recommendations were incorporated in the final plans.

This brief statement of experience in one city is included only to indicate how quickly confidence and coöperative effort may be established. Sound engineering advice is appreciated and will command respect. It is frequently suggested in connection with schools, housing, water supply problems, etc., that "the health officer should advise the appropriate officials on matters concerning public health." Unless backed by study and a knowledge of the

principles involved, such advice is not specific enough and frequently is overlooked until too late to mean much. Plans submitted after construction has gotten under way or even after the plans are complete cannot be readily changed. This is just as true for schools as for water supply improvements.

It would serve no useful purpose to list herein the detailed technical features to be covered in school building design and equipment, for these are readily available in current standard texts. It is important, however, to emphasize and reemphasize that a sound coöperative program between the health and education departments must be based on the respect and confidence of the board of education and on the obvious qualifications and tactfulness of the health officials for dealing with the environmental problems. The minimum necessary steps to provide the satisfactory physical structure and equipment are as follows:

1. Survey of the school plants (master survey)

2. Yearly inspections plus coöperative assistance from the nurse

3. Definite reports and recommendations to be made at the right time in order to receive consideration when the budget is being planned

4. Approval of plans by the public health engineer, in consultation with the school architect

5. Preparation of specifications for sanitary equipment, such as fountains, syphon breakers, dish washing equipment, new lighting systems, etc.

6. Active interest in the educational material used in teaching public health in the school

When peace comes, the school will be revived. New and delayed structures will be built. Now, however, is the time for the health department to make its joint plans with the school department for the introduction of sound, economical, and safe standards and practices into the school environment. This is one field where simple familiar structures and equipment should not be forgotten because they fail to stir the imagination of the crusader. They do protect lives and safeguard well-being.

Resources of Industry for Health Education*

HOMER N. CALVER, F.A.P.H.A.

Secretary, Public Health Committee of the Paper Cup and Container Institute, New York, N. Y.

INDUSTRY is a vast and complicated machine. Beside it our public health structure has an embryonic simplicity in spite of the miscellany of societies, associations, councils, committees, funds, foundations, institutes, departments, services, and bureaus with which we are familiar. The resources of industry in men, money, and experience are of course enormous, but these must be applied to creating production, jobs and profits. When its resources are applied to health education, that is incidental to its fundamental purposes. Health education is not an end in itself for industry as it is for health educators. In spite of this diversity of approach the two groups can work and have worked together for mutual advantage.

Industry provides organized and reachable groups of people to work with. It spends large sums for advertising, publicity, and promotion, of which millions of dollars are aimed at education of the public in matters of health and sanitation. Health educators in general have been prone to watch industry's health education efforts from afar with scorn, approval, condemnation, criticism, or compliment after the effort has occurred. Seldom have they tried to guide these efforts. On the whole health educators have been

quicker to condemn the bad than to accept the good. But the results might more often be good if health educators would take positive, aggressive action to make them so.

For example, I have seen a pamphlet published by a manufacturer of a commodity which every public health worker would agree had unmistakable public health value. The pamphlet had good art work, clear type, an excellent editorial style. Great and expensive talents had gone into the preparation of a piece of educational literature which in attractiveness and effect seldom is equalled by non-commercial publishers. However, in his zeal and ignorance, the manufacturer had made health claims for his product which were not scientifically justified. And, moreover, with a dim consciousness that a health officer might be looking over his shoulder, he failed to stress values of his product that were wholly sound both from selling and educational standpoints. That publication was rejected by health educators. It failed to have its fullest value for the manufacturer. Here was a resource of industry for health education which was wasted both for health education and for industry.

Recently the government in its nutrition campaign has shown in a big way how business resources can be tapped for health education purposes. Millions of business promotion dollars have been spent under the direction of

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

the Food Distribution Administration for nutrition education. As a result public funds were conserved, coöperating businesses were flattered by the implied partnership, and the nutritional message reached the people promptly and effectively.

Long ago the Metropolitan Life Insurance Company demonstrated with its Educational Advisory Committee how a business organization can team up with health education for the benefit of itself and the public health.

These are two patterns of coöperation which could be extended to other fields. Other patterns to meet other conditions can be devised. Constructive action of this character is the best antidote for objectionable advertising.

In the last analysis health depends to a very great extent on things which are bought and sold. There is hardly a health education message which is not a promotion for one or more products of industry. For instance—Drink pure water—has meant business for the manufacturers and purveyors of cement, pipe, fixtures, and purification apparatus.

Drink more milk—brought more business and better prices to farmers, breeders, feed producers, dairy equipment suppliers, and even carpenters and masons to build barns and silos. When we insisted on pasteurizing milk, that opened a whole new field of profit. Our laws and regulations on dishwashing in public eating and drinking places if enforced mean more business for the purveyors of soap, detergents, chemicals, hot water heaters, tanks, racks, and laundries.

Furthermore, if industry were not ready to provide the capital and take the business risk involved in producing these essentials for the public health, many of our educational recommendations would be incapable of fulfillment.

Since it is clear that many industries could not exist without the public health

program and that public health requirements could not be met without industry, it is hard to understand why such a gulf exists between the two fields. Speaking as a health educator, it seems to me that we should have no hesitancy in requesting an industry to aid us in a program without which that industry might never have come into being. And speaking for industry I see no reason why it should not ask health educators to assist it in health education programs which after all are the educator's chief concern. The Public Health Education Section could most appropriately take the initiative in bringing about such a coördination of effort, which would tap tremendous new resources for health education.

If such collaboration is to take place it may be profitable to examine the organization of industry as it exists for this purpose. There are:

1. The individual manufacturers, producers, processors, and converters with their wholesalers, jobbers, retailers, and distributors—Examples in this class are: General Electric Company, Campbell Soup Company, Lederle Laboratories, and United Fruit Company.

2. The service organizations, including public utilities—Examples in this class are: The American Telephone and Telegraph Company, New York Central Railroad, John Hancock Mutual Life Insurance Company, American Railway Express.

3. The trade associations—Usually these are horizontal combinations of competitive companies in the same field, such as: The American Soap and Glycerine Manufacturers Association, the American Meat Institute, Portland Cement Institute, California Association of Citrus Fruit Growers.

4. Agencies which are especially created by industry groups for research, educational and promotional purposes, such as: The Portland Cement Association, National Dairy Council, the former Cleanliness Institute, and the new Nutrition Foundation.

5. The advertising and publicity agencies employed by industry, among which some of the better known are: Young and Rubicam, J. Walter Thompson, Edward L. Bernays, and Ivy Lee.

In each of these categories there are

many organizations whose business advantage is so closely related to public health progress that there should be little difficulty in quickly developing mutually advantageous coöperative programs.

In the meantime, how can health educators utilize the resources which already exist? Most of us are aware of the availability from industry of a great wealth of pamphlets, posters, movies, and other auditory and visual aids. In spite of the constant efforts of the producers of this material to secure its wider use, the worker in the field often does not know of its existence and at a distance is unable to determine its value for his particular situation. The American Film Center has helped to meet this need in the motion picture field by publication of its annotated list of health films for lay audiences. Until similar compendiums of information on other types of materials are prepared it will be necessary to rely on the information offered from time to time in the magazine *Channels* and in the *American Journal of Public Health*. Unfortunately there is no central agency which continuously makes it its business to see and evaluate health education materials. Nevertheless most of the large national voluntary agencies, including the National Health Library, can usually give some information on resources or suggest other points of inquiry. Undoubtedly the best single source of information is the National Publicity Council and its regular exhibits at the A.P.H.A. meetings. Its information relates to materials from all sources, including industry. It must be remembered, however, that in all information received from such central sources, there has been a conscious or unconscious evaluation of the material in question by the individual who answers the inquiry. This usually makes it desirable to secure information from several sources, and necessary to interpret

recommendations (which may be conflicting) on the basis of one's own judgment and knowledge of the conditions under which the material is to be used. The time does not seem ripe for developing a "Seal of Acceptance" for health education materials, such as exists for drugs, foods, and therapeutic devices. In the meantime, Dr. Bauer, Dr. Galdston, and others^{1, 2, 3} have suggested certain broad criteria to guide us in the selection of material.

In addition to the *materials* which industry can furnish us for our use we should not overlook the fact that industry also offers great groups of men and women to work with. These groups are organized and reachable. Many big industries have developed their own programs of health education, though these have frequently been limited to safety education. Organized labor also has a growing interest in health education. But a great opportunity still exists for health educators to broaden the safety message into a general health message and to work with large and small groups of workers in the same way that they have learned to work with other organized and reachable groups.

Although industry offers materials for our use and groups that we can reach, it has another resource of far greater potential value than either of these. This is its advertising in newspapers, magazines, radio, and elsewhere. Use of the health appeal in advertising is not new. The following about a then popular dentifrice is from *Peterson's Ladies National Magazine* for 1877:

Among all the disagreeable consequences that follow the decay of the teeth, an impure breath must be the most mortifying and unpleasant to its possessor, and it is the most inexcusable and offensive in society; and yet the cause of it may easily be removed by cleansing your teeth daily with that justly popular dentifrice, Fragrant SOZODONT. It purifies and sweetens the breath, cools and refreshes the mouth, hardens the gums, and

gives a pearl-like appearance to the teeth. GENTLEMEN WHO INDULGE IN SMOKING should cleanse their teeth with SOZODONT, as it removes all unpleasant odors of the weed. Sold by all Druggists.

Because of claims like this and others which were not well founded, health educators have been justified in their skeptical view of much of the material relating to health which has commercial sponsorship. But many changes have occurred since 1877. Fifty years later *Better Times*⁴ editorialized on the excellence of the campaigns and materials which were then emanating from commercial groups. Since then Dr. Bauer and others have pointed out that advertising is not necessarily bad health education just because it is advertising.

Nevertheless, I think all here will agree that much of the present-day advertising is still somewhat less than perfect from the health education standpoint. As far as health education is concerned, it is a resource that is frequently going to waste, if not worse. One might overlook this waste if it were not so tremendous.

To us who are accustomed to modest budgets its size is truly staggering. A quick review of the ten magazines of largest circulation for the month of September, 1943 (counting only one issue of each weekly) indicates that approximately half of all advertising stressed or featured health in one way or another. These ten magazines had a gross circulation of approximately 32½ million copies. The first twenty have a gross circulation of more than 50 million copies. Assuming two readers for every copy, which advertisers consider a small estimate, and counting the weekly publications four or five times a month, the gross readership of twenty leading national magazines is better than 150 million a month. When one adds to that the impact of hundreds of lesser publications (including the pulp magazines), newspapers, radio,

car cards, billboards and other mass media, it is obvious that through advertising, the equivalent of every person in the United States is reached not only once, but many times a month. And even if we do not extend our computation for the ten largest magazines in which half of this advertising deals with health, we still have a minimum audience of 60 million people every month in the year. No one will doubt that this is considerably more than the combined total reached by all of our official and voluntary agencies through all of their channels.

September is not one of the biggest advertising months, and the war theme which runs through much advertising today serves to curtail the amount of health advertising. Nevertheless, some 2½ million dollars was spent on health advertising in this one month (again counting weeklies only once) in just ten magazines. This is at the rate of 30 million dollars a year. What the annual figure would be if one included all magazines as well as other advertising media I have not computed. These figures are enough to indicate however that the impact of advertising is, to put it mildly, somewhat greater than the impact of professional health education. Elsewhere I have commented on this comparison and raised the question whether health educators or advertisers are going to do the job of health educators.⁵ If anyone believes that the impact of advertising is merely massive and not effective, consider the wide use of laxatives against the recommendation of the medical profession. I suspect that even in this group more of us drink orange juice for breakfast because of what we saw in the advertisements than because of what we read in the textbook. Here, then, is the greatest single resource of industry for health education and it is being used largely without our help and often without our blessing. It constitutes our biggest challenge

today. We must look for a way to use this resource for a healthier nation.

Dr. Cumming Receives the William Freeman Snow Award

The American Social Hygiene Association has announced the recent award to Hugh Smith Cumming, M.D., Director of the Pan American Sanitary Bureau, Washington, former Surgeon General of the U. S. Public Health Service, of the William Freeman Snow Award for distinguished service to humanity. The award was presented in recognition of Dr. Cumming's 50 years of public health service, during the entire period of which he has been identified with the U. S. Public Health Service.

Dr. Cumming is a graduate in medi-

cine of the University of Virginia in 1893, and has received honorary degrees from the University of Pennsylvania in 1930, and from Yale in 1933. He served as Surgeon General of the U. S. Public Health Service 1920-1936. He has been Director of the Pan American Sanitary Bureau since its organization in 1920 and has been a member of the Health Committee, League of Nations, since its creation and Vice-President since 1937. Dr. Cumming served as President of the American Public Health Association in 1931.

Modern Malaria Control*

MARK D. HOLLIS

*Sanitary Engineer, U. S. Public Health Service Executive Officer,
Malaria Control in War Areas, Atlanta, Ga.*

THE word "modern" in the title of this paper is almost superfluous because all technical malaria control practices are relatively new. Herms and Gray, the authors of the modern text on the subject, were both prominently identified with the first anti-malarial mosquito campaigns in the United States as recently as 1910.

To the engineer malaria control measures involve the mechanics of reducing exposure of the human host to the potent vectors of the disease. This is accomplished by controlling production of the vectors through attack on the aquatic stages, segregation by mosquito proofing, house spraying to destroy the adult engorged female anopheline, and the use of repellents. Chemotherapy and prophylaxis by drugs are excluded as control media. In reference to this, a recent release from a national committee on tropical diseases states in part:

Malaria infection rates have never been controlled by drugs. If malaria control is the proposed purpose of suppressive treatment, then it is not advisable. . . . Wholesale suppressive treatment would only serve to increase the number of sub-clinical cases. It is much better to let attacks become apparent through frank paroxysm and then give full therapeutic medication. . . .

Pending discovery of a drug or a biological preparation harmless to hu-

man beings and completely efficient in destroying the parasites in the blood, the control of mosquito vectors remains the most effective means of reducing the infection rate.

Undoubtedly, the easiest method of malaria control is by the depopulation of an area. Where malaria is hyper-endemic, this is apt to be the natural course of events as the birth rate invariably falls below the death rate. Many peoples in highly endemic areas have learned by experience, folklore, or tribal taboo to depopulate certain areas during that portion of the year when transmission is probable. The hillmen of the Burma Road country depopulate the valleys at night during the warm parts of the year, thereby remaining a relatively healthy, vigorous race as compared with the malaria-ridden tribes of the lowlands. The Tennessee Valley Authority, a leader in modern malaria control practices, has used with success the general principles of depopulation. For example, in certain areas where the control of the malaria vector is economically infeasible, "night leases" are negotiated which permit land utilization during daylight hours but forbid trespassing by night.

Basically the technics of controlling production of mosquitoes have changed but little. Larviciding, filling and draining of standing water remain the cardinal principles involved, but refinements have made our present-day procedures more efficient and economical.

The first break in the old practice of

* Presented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

using any available petroleum oil as a larvicide was the recognition and adoption of oils having known toxicity, satisfactory spreading qualities, and a degree of volatility that would assure some hours of maintenance. Determination of these qualities can be made in the field with very simple equipment.

In 1921 Barber and Hayne published their trials with Paris green as a dust applied to the water surface to kill anopheline larvae. King and Bradley adapted the method to airplane dusting in 1925. Pyrethrum was introduced in an oil emulsion by Ginsberg for special uses.

Present war needs and the attendant threat of oil and Paris green shortages have accelerated the search for a more perfect larvicide. Within the last few weeks there have been enthusiastic reports on a new insecticide. According to preliminary reports application of unbelievably small amounts of this material effect control which persists for a period of time much longer than that obtainable by use of our present-day insecticides. One report, which smacks of facetiousness, records the destruction of anopheline larvae in a control pool by the inadvertent passage from a treated pool to the control pool of a flock of ducks.

It is almost axiomatic that all new insecticides make their initial appearance heralded by the statement that here at last is an "insecticide to end all insecticides." Time records few of them, however, that do not develop insurmountable obstacles to their effective use. Let us hope that this particular one is an exception. If it will accomplish one-half of what is now claimed for it, it may well prove to be one of the outstanding salvage values of the war.

Draining and filling as applied to mosquito control are engineering practices that change as little as the laws of hydraulics. In the main, anti-

malarial drainage proceeds through three stages:

1. Temporary ditching to draw off surplus water so that the terrain may be worked
2. Semi-permanent ditches, excavated to grade, sloped, smoothed, and otherwise made adequate for immediate mosquito control purposes but requiring annual maintenance
3. Permanent structures such as concrete inverts, lined ditches, and underground drains

For installations in endemic areas the ultimate, and eventually the most economical, solution is the permanent type of construction. However, for emergency work or for areas of doubtful permanency such construction may not be justified. For the same energy much more semi-permanent work can be achieved. Further, where the balance between transmission and non-transmission is slight, as is often the case in areas of low endemicity, the construction of semi-permanent ditches is all that is needed to overbalance the scales in favor of non-transmission.

In impoundments the full development and practice of cyclic water level fluctuation has been a notable factor of recent years. For smaller impoundments automatic syphons have been used with success.

One of the most progressive improvements in malaria control practice has been the introduction of species sanitation. Formerly control of malaria mosquito production was largely by general mosquito control. The procedures established in the last war constituted one step in advance in that they prescribed the drainage only of standing water which produced anopheline mosquitoes. Today we have rather firmly established the point that in continental United States, out of the twelve species of the genus *Anopheles* capable of transmitting malaria in laboratory trials, only three—*A. quadrimaculatus* in the East, *A. freeborni* in the West, and *A. albimanus* in the Rio Grande Valley, are found to be significant vectors. With this information as a guide,

the present mosquito control team consisting of an engineer and entomologist can survey an area and eliminate from further consideration great acreages of standing water that would have been included previously in control operations.

Particularly striking in this respect are the enormous expanses of cypress swamps in which breeding of *A. crucians* is intensive throughout their extent, but in which *A. quadrimaculatus* occurs only in trifling numbers. The latter can be controlled by dusting or spraying the sunlit edges where this species may reproduce. The economy of this practice becomes immediately obvious. I might here interpolate, with due humility, that the engineering profession has gradually accepted the entomologist in an associated partnership. The history of the present emergency control program should firmly establish the entomological malariologist as an essential entity of the modern malaria control team.

As you know, malaria transmission is dependent on simultaneous occurrence of human cases of the disease and potent anopheline vectors. Malaria vectors occur in practically every state in the union. Also, it is probable, particularly with the dislocation of populations by movements of armed forces and migrations of war workers, that human malaria carriers have been widely scattered throughout the nation. However, there has resulted, as yet, no noticeable extension of the endemic centers of malaria.

The reason for this is found in a third factor which must be present in order to produce endemic malaria—the proper “ecologic niche.” This properly vague factor is a combination of natural and man-made circumstances. If favorable, these circumstances help to overcome the mathematical odds against transmission. If unfavorable, they lengthen the odds and make trans-

mission more difficult to the point where it approaches mathematical improbability.

A review of a simple case may help to illustrate the importance of this point. Malaria is a disease of warm countries. Its distribution makes this obvious; the optimum temperatures for the development of the parasite in the body of the mosquito, ranging from 71°–86° F. depending on the species of *Plasmodium*, confirms the point. With the same combination of mosquitoes and human carriers, the parasite is going to have a much smaller chance of striking favorable temperature conditions for its development in mosquitoes in northern Michigan than in southern Georgia. If, in addition to the unfavorable temperature, the few parasites that are ingested in warm, favorable periods of weather find themselves in the bodies of mosquitoes that inhabit well screened communities, the chances are that the parasite will be pumped into oblivion in the blood stream of non-human hosts.

From this it is apparent that as the natural environment for the propagation of mosquito vectors and the malarial parasites approach optimum conditions, the more stringent must be the artificial protective devices. Conversely, of course, the more unfavorable the natural conditions, the greater will be the effect of small expenditures of time and effort on malaria mosquito control or protective devices.

Herein probably lies the reason why endemic malaria is now largely confined to the southeastern portion of the United States, with the exception of a few isolated areas such as the valleys of California, Oregon, and New Mexico. In some cases, conscious mosquito control operations have hastened the decline of malaria in the regions outside the present endemic areas. In the main, however, these areas have “outgrown” their malaria unconsciously through screening, agricultural drainage or

reclamation, improved housing, and intensified use of the land.

In endemic areas these incidental measures do not interpose sufficiently adequate hurdles to prevent continued transmission and we must resort to control measures specifically designed to meet the needs of the situation.

Up until the last war the Cuban and Panamanian demonstrations were not applied to any extent in this country. A decided impetus was given to interest in anti-malaria measures at the community level by the program executed in extra-military zones during 1917 and 1918. This U. S. Public Health Service program extended to 43 areas in 15 states over a total area of about 1,200 square miles. It demonstrated the values accrued, and trained a relatively large group of technical workers for civilian employment in this field.

Since 1918 there has been a progressive strengthening of antimalaria organizations in the southeastern states. The annual number of cases has steadily declined as control efforts and improved living conditions have removed the disease from the cities and larger towns and from many smaller communities. Thus have been removed the worst foci of infection from which malaria spreads epidemically during that part of its biological cycle when its virulence and intensity are increasing.

The secondary impetus furnished malaria control by the various works relief programs in the "thirties" doubtless aided the recession of endemic areas. During this period over 86,000 miles of drainage ditches were constructed in the southeastern United States. With man power and materials of little consequence, the prime objective of the time was the elimination of breeding areas by antimosquito drainage.

The advent of the present war emergency, with the concentrations of military and industrial mobilization in

malarious areas, necessitated anti-malarial measures to prevent the expected cyclic rise of the disease. This program, Malaria Control in War Areas, a joint undertaking of the U. S. Public Health Service and the several state health departments, is designed to control production of malaria mosquitoes and reduce potential malaria transmission in extra-cantonment zones of military and essential war industrial areas. It is emergency malaria control; a program of preventive medicine. The guiding policy is to provide effective protection with a minimum expenditure of man power and material.

The program complements similar activities of military authorities within the reservation limits. At present, control operations are carried out at 1,200 war establishments located in 22 states, the District of Columbia, and Puerto Rico. In the past year, 13,000 acres were cleared for larvicidal operations, about 5,000 miles of ditches were cleaned, and over 5,000 acres of breeding surface were eliminated by 1,100 miles of drainage. Over 12,000 lineal feet of ditches were lined with durable materials. About 7,000 lineal feet of underground drainage was installed. In this construction one-half million pounds of dynamite were used, as well as draglines, bulldozers, and other power equipment. In the larvicidal operations, airplane dusting, together with heavy power equipment mounted on boats and trucks, aided in conserving man power.

Full advantage is taken of entomological science and the practice of species sanitation. In many areas entomological surveillance replaced costly control operations.

As yet little public information is available on malaria control methods as practised by the armed forces under combat conditions. A review of war theaters leaves little doubt that malaria is the number one disease confronting

our military leaders. The history of malaria in World War 2 will make interesting reading.

The extensive antimosquito drainage of the "thirties," the highly scientific emergency program at present, together with the military experience abroad, should provide the background from which will emerge modern malaria control as a true science. Fundamentals are well established; the overall prospectus is clear. It remains only for competent leadership in the medical, entomological, and engineering professions to translate these fundamentals into practice. The cardinal principles of modern malaria control will be an associated partnership of these three sciences, full development of species sanitation, intelligent integration of basic control principles into modern developments, recognition of conservation interests, and full use of educational media to stimulate individual and community effort. The day of the amateur malariologist will be past. Malaria control no longer will be simply "pouring of oil" or "digging of ditches." It will consist of highly trained men working in a coöordinated and supervised organization. Eradication of *Anopheles gambiae* in Brazil has demonstrated the effectiveness of an efficient organization.

It may well be that the next major

challenge to the malariologist in the United States will result from the impact of large numbers of returning troops from malarious areas. Dr. Louis L. Williams, Jr., of the U. S. Public Health Service, has proposed a challenging hypothesis—that of eradicating malaria from continental United States. Dr. Williams proposes an anti-anopheline attack in the persistent endemic areas and the activation of mobile antimalaria units to control the expected explosive outbreaks that are anticipated in those areas outside the endemic foci. More will be heard of this proposal in the near future.

Malaria in humans is a disease. The medical profession must take responsibility for overall leadership. Having determined vector control essential, medical science defines the endemic foci, the entomologist determines the density and breeding areas of the malaria vector; the engineer applies the mechanics of engineering science to accomplish control. Where the related principles of all three sciences are not coöordinated there is sacrificed effectiveness or efficiency, or both. The future outlook for malaria prevention is good. Its ultimate eradication from the continent is well within probability. Time will tell what use is made of these opportunities.

The United States Chamber of Commerce Public Health Program *

HOWARD STRONG

Special Representative, Insurance Department, Chamber of Commerce of the United States of America, Washington, D. C.

THE United States Chamber of Commerce believes that all businessmen should be, and it knows that many are, interested in national and community health and particularly, of course, in industrial health. The Chamber with its 2,000 organization members, is in a position to stimulate this interest and to secure layman support for the national and local health programs, the major responsibility for which must certainly rest with the federal, state, and local health departments, with the voluntary health agencies, and with the medical profession.

The Chamber of Commerce health program has, of course, certain definite limitations and, I think, definite possibilities. We cannot, nor shall we try to contribute to technical health knowledge. That is the job of the laboratories, the research institutes, the medical and health agencies—public and private—and the medical, dental, and engineering professions. We certainly shall not presume to tell the doctors what to do—they must tell us. But the program, we hope, can contribute materially to the spread of the knowledge which we have and to its application and use—an application which you know better than we, has lagged far

behind the usable knowledge and technics which are available.

The Chamber health program is under the supervision of our Health Advisory Council, which is made up of thirty-two outstanding authorities in the medical and health field, with Dr. James S. McLester as General Chairman, Dr. W. G. Smillie, as Chairman of the Community Health Committee, Dr. Leverett D. Bristol, Chairman of the Industrial Health Committee, and Dr. James E. Paullin, Chairman of the Individual Health Committee.† These are men whom you all know, and in whom you have confidence. We realize that our work must be done with and through the U. S. Public Health Service and other federal agencies, the state departments of health, the local health departments and medical societies, and the great voluntary organizations such as the American Public Health Association, the American Medical Association, and many specialized agencies. We shall count on you to keep us within the bounds of professional soundness.

Our major job, then, is to assist in public education and to secure layman support for the activities which you will develop. My experience indicates that too many businessmen and laymen look on community health ac-

* Presented at a Joint Session of the Industrial Hygiene and Health Officers Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

† Dr. Bristol has recently succeeded Dr. McLester as General Chairman, and Dr. Anthony J. Lanza has succeeded Dr. Bristol as Chairman of the Industrial Health Committee.

tivities as an expression of an overdeveloped, and perhaps not fully warranted, professional enthusiasm and the health department as a useful luxury, but not always as a major essential service. We must help to establish the validity of the health program and assist in creating an insistent community demand for the knowledge and services which you, the professional men and women, are in a position to provide.

The American Public Health Association in its declaration of Desirable Minimum Functions and Organization Principles for Health Activities says, "Health departments should be responsive to public demands. The scope and policy of public health work will depend upon the stage of development of medical, sanitary, and related sciences, and upon *the readiness of the public to support their effective use.*" This implies, of course, the existence of such a demand. Cannot the layman's organization be useful in creating this demand on the part of the community, to which most health departments will readily respond if that demand is coupled with the assurance of financial support sufficient to meet it? We must help to create a willingness that tax money shall be spent to supply the services which are available. And cannot such an organization, too, assist in establishing sounder public relations for the health department, a better understanding of its work and its needs, a closer relationship between the citizens and their official medical staff?

The National Chamber health program, as it is developing, seems naturally to fall into two categories.

1. EDUCATION

Printed material, always professionally approved, of course, will be prepared for widespread circulation. This may include a periodical dealing with current health subjects of interest

and importance to the layman, for distribution among workers and to homes and citizens generally; timely news releases and articles for newspapers and a variety of house organs and magazines; subject matter for radio and public addresses; and specialized material from authoritative sources, or our digests of such material, for distribution to special audiences. This educational material should cover all major phases of health knowledge and practice, with special emphasis on industrial health, and with particular attention to women in industry and the children of working mothers, nutrition, tuberculosis, and venereal disease, the expansion and support of hospitals and constant effort to strengthen and support local public health services. It must, of course, carry an editorial style and text adapted to the specific levels and audiences which are to be activated. Such an educational program should bring not only a better understanding of ways to sounder health but should help to create a demand and supply the means to provide for the services necessary to realize our objective.

A prospectus outlining this program has been distributed to leaders of public thought throughout the nation and to organization executives.

2. ACTION

It is not enough to create an intelligent understanding. This understanding must be translated into action, particularly at the community level. The modern Chamber of Commerce does not limit its activities to the interests of business alone. It is concerned with every activity which makes for the welfare of the whole community. Hundreds of chambers of commerce have set up health committees, composed of physicians and laymen, which are effective instruments in securing community understanding and backing for the health department and its program, and

which sometimes, it must be added, have been useful in stimulating the health department to undertake a broader field of activity. This phase of the National Chamber program is being directed not only to local chambers of commerce, but to health councils and other community organizations which are or should be interested.

In the development of any community health program, it is our feeling that the first step is to know the facts, to make an inventory of current health activities and needs. The National Health Honor Roll which, for fourteen years, has been conducted by the American Public Health Association and the National Chamber, provides an effective means for such an inventory, with its *Evaluation Schedule* and its analysis supplied to each participant. We hope that the Honor Roll may become less an effort to obtain distinction and the national recognition which goes with it, and with the communities sometimes resting on their laurels when they have obtained a place on the Honor Roll. It should become more a stimulus to aggressive action, with the evaluation schedule and the analysis as guideposts to the next steps which must be taken toward the fulfillment of a well rounded and adequate program. We expect the Honor Roll to be continued as a major project in the Chamber's health program, and with this objective definitely emphasized.

Two methods of approach are being used in this action phase of our program—the shot gun and the rifle. We are sending to all member community organizations, and others as we make contact with them, material which we trust will be definitely helpful in securing local action and in intelligently guiding that action. A booklet outlining practical methods for setting up a community health committee or council and suggesting the major activities which should be included in the pro-

gram, has been distributed to these organizations. The Committee on Administrative Practice of the American Public Health Association has revised the *Evaluation Schedule* and simplified the procedures to adapt them to wartime pressures. A pamphlet setting forth the procedures, together with entry blanks, has been sent to all member organizations. Special effort is being made to secure wide participation in this activity. A plan for joint medical services for small industries and an industrial medical self-evaluation schedule, prepared by Dr. Leverett D. Bristol and Dr. Anthony Lanza, will be made available to industrial and other employers. A pamphlet on nutrition, with special emphasis on its industrial phases, is under way, and the Council is coöperating with the War Production Board and the War Food Administration in the distribution of effective material in connection with the "Food-Fights-For-Freedom" Campaign.

The first issue of an occasional bulletin emphasizing various aspects of the Community Health Program and reporting actual accomplishments in this field, is being prepared. This will go to organization executives. Other documents are being planned and will be developed as additional needs indicate. These publications are interspersed with individual letters and occasional personal visits. Thus a widespread effort to create a broader community interest in public health is being put forth. This is the shot gun method.

We have felt too that the Chamber can well select certain communities for special service in intensified local programs and use these communities as demonstration areas to serve as an example and inspiration to others. These programs can become foci of infection for extending community health thinking and action to other centers. A group of New England organization

executives has already met to consider this proposal, and several are now making plans for an intensive program. State health departments have agreed to coöperate and give their assistance. Other groups will be called together and we believe that a considerable number of communities can, in this way, be stimulated to increased action. The assistance of a number of national organizations in these local programs has been assured.

The Council is also developing a consulting service to assist communities in solving their special health problems. Technical questions will be referred to members of the Council or to professional organizations and individuals. We believe that we, in the Chamber, can be helpful in this way.

Thus are we using the rifle method, picking out our target and aiming at the bull's eye.

In all of this activity, most certainly, the health of the worker, who is the backbone of our national prosperity, must be emphasized.

Now may I suggest a project which, it seems to me, would stimulate an orderly national and local health program, and upon which I should like to have your thinking.

After many years of effort, as you all know, every state in the Union has passed laws requiring the reporting of vital statistics. As this reporting becomes more complete and efficient, a vast store of statistical information is being accumulated and is proving of inestimable value as a background against which our public health program is being planned and carried forward.

The American Public Health Association has demonstrated the efficacy of an annual evaluation of the health activities of a community with full-time health services, not only as a measure of accomplishment, but as a directive for future action. Is there not some way in which other communities also could enjoy the benefits of this annual appraisal? I am thinking particularly of those communities which do not have full-time health services. May we not look forward to a universal annual or biennial evaluation of the health services of all our community health departments? Such an evaluation would be conducted under the aegis of the state health departments and be brought together by the U. S. Public Health Service or some other central agency, as a measure of current activities and a guide and directive for future action. Perhaps this evaluation would serve as a stimulus to better equipped departments and more extensive public health protection. The significant work of the American Public Health Association in this field could well attain its logical fruition in such a national policy. It would be a long and arduous task, and it is, perhaps, a somewhat idealistic proposal, but I think it well worth serious consideration.

I have outlined an ambitious program and many other activities will develop as we go along. The program cannot be realized immediately, nor can it be realized at all without the guidance and help of you who are carrying the torch in the field of community and industrial health. The Health Advisory Council hopes and believes that we shall have that guidance and help.

Newer Procedures in Laboratory Diagnosis and Therapy in the Control of Bacillary Dysentery*

ALBERT V. HARDY, M.D., DR.P.H., SURGEON (R) AND
JAMES WATT, M.D., DR.P.H., SURGEON

*Division of Infectious Diseases, National Institute of Health, U. S. Public
Health Service, Washington, D. C.*

THERE has been recently a renewed concern for the acute diarrheal diseases and, concurrently, a substantial advance in the knowledge of these disorders. It is the purpose of this report to review this newer knowledge as related to the problem of control.

GENERAL OBSERVATIONS

Rational control of disease rests upon reliable diagnoses. To obtain these in the diarrheal diseases, a revision is needed of the prevailing concept of the clinical characteristics which warrant a consideration of *Shigella* infections. In our clinical series of 555 proven positive cases, the most frequent manifestation was a "simple diarrhea." The classical bloody mucoid stools were notably infrequent; indeed, these scarcely entered into the clinical picture of Sonne, Schmitz, or mild Flexner infections, and were not a prominent feature in severe Flexner cases. Also the onset was marked quite frequently by a prominent fever but only mild enteric symptoms, suggesting "flu" rather than dysentery. The very name bacillary dysentery accounts for many

of the missed diagnoses. A designation referable to etiology and freed of its present misleading clinical implications would be preferable. We therefore use and recommend the name "shigellosis" for all infections due to pathogenic *Shigellae*. Thus shigellosis is to be thought of as a possible, and in many areas as the most probable, diagnosis in the common variety of acute endemic diarrhea and in an uncertain proportion of cases so loosely designated "intestinal flu."

The manifestations of shigellosis vary widely. In the young the illnesses are frequently grave, occasionally fulminating, whereas in older children and adults the disorders are usually mild. Furthermore, in the young, *Shigella* infection ordinarily results in definite illness, while in older children, adolescents, and adults very mild disorders and subclinical infections are much more common than significant clinical disease. Furthermore, regardless of age of the patient or severity of the disease, infection usually persists beyond clinical recovery. The duration of the convalescent carrier state is commonly three to four times that of the total duration of symptoms. For control, due attention must be given to carriers, convalescent and passive, and

* Presented at a Joint Session of the Epidemiology, Health Officers, Maternal and Child Health, and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

to cases with disturbances of little clinical significance.

Shigellae may be spread in various ways; the relative importance of these must be weighed in formulating control procedures. We found no evidence, in our own experience, which suggested water-borne infection. Milk was notably free of suspicion, since the poor, who suffer most from diarrheal diseases, generally purchase the less expensive canned or dried product. There was some evidence of spread through contaminated food, but this appeared of minor rather than major importance. Where it did occur, usually multiple carriers were found among the food handlers and kitchen helpers. The disease and flies did thrive under similar conditions. Still, cultural evidence suggested that flies rarely harbor viable *Shigellae*. We isolated this organism from flies only once in repeated trials. In contrast we recovered these pathogens with comparative ease from the fingers or from under the finger nails of known cases and carriers. Considering all evidence we are of the opinion that *Shigellae* are transported from group to group through the movement of infected individuals. Within the household and in other groups living together the organisms are most commonly passed from person to person through direct or indirect contact. Among institutional inmates the negative evidence excluding other channels of spread was strikingly clear in several outbreaks. Hence the control of infected individuals (including personal cleanliness) is of much greater importance in the prevention of bacillary dysentery than has been believed.

Explosive epidemics of shigellosis suggesting a common source and single exposure are rare. Ordinarily, an epidemic starts with sporadic infections which gradually become more numerous, the early cases preceding the recognized outbreak by 2 to 4 weeks

or more. The total prevalence, which increases gradually, usually reaches a level of between 10 and 33 per cent. Total incidence of primary attacks (clinical and subclinical) in unmodified outbreaks may approach 100 per cent and counting reinfections has gone even beyond this. Clinical cases, which are most numerous early in the outbreak, decline promptly following the peak of the epidemic, but the total prevalence decreases slowly because of persisting convalescent and passive carriers. The duration of an unmodified outbreak is weeks rather than days. Obviously, throughout this prolonged period a rich source for the spread of infection is maintained. The slow evolution of *Shigella* epidemics provides the need and the *opportunity* for the application of control measures.

LABORATORY PROCEDURES

The advances here have resulted in a simplification of bacteriological technics and a marked increase in the reliability of cultural tests. The development and introduction of the highly selective media which grow the enteric pathogens while inhibiting almost all the non-pathogens was of major importance. Earlier we used desoxycholate-citrate agar, now we employ S. S. (*Shigella*-*Salmonella*) agar which has grown satisfactorily all strains of *Shigellae* encountered. In the study of known *Shigella* outbreaks this culture medium only is used for primary plating. A heavy fecal inoculation may and should be employed; to obtain this the usual cotton-tipped applicator coated with feces is satisfactory. This makes it convenient and practicable to collect specimens by rectal swabs and to inoculate the plate directly by "painting" the entire surface of the agar with the swab. The device for taking the rectal swab which we recommend is a small rubber tube large enough to contain the cotton-tipped applicator. The

distal end is cut on a bevel and its external surface is lubricated before use. The applicator alone can be used for infants; in adults, also it may be inserted with little discomfort if the cotton tip is moist. The collection of fecal material for culture by this method involves only the skill required in taking rectal temperatures. The whole procedure is so simple that the responsibility for obtaining and plating of cultures can be entrusted (following instruction and demonstration) to a nurse, attendant, or technician.

This procedure opens a new approach to control. It is now practicable to culture large numbers of individuals for the identification of carriers of *Shigellae*. The plates, prepared and numbered, the sterile swabs, lubricant, and record sheets are taken from the laboratory to the group to be cultured. There the responsibility is divided, one person taking the swabs, a second inoculating plates, a third writing names and culture numbers, and one or more preparing the patients. When the latter are ambulatory, cultures are taken at one place, the patients coming in line, bending over while the swab is being obtained, and leaving by a separate exit. If the work proceeds smoothly, cultures can be taken at about the rate of 200 per hour. It requires more time to handle patients in bed where the materials must be taken from ward to ward. In the presence of an outbreak, the individuals being cultured rarely object, providing the swab is taken by a considerate person of the same sex.

Simplified steps recommended for a prompt and reliable identification of pathogenic *Shigellae* in an identified outbreak are as follows:

Suspicious colonies are picked to Kligler's iron agar (Russell's double or Krumwiede's triple sugar agar is satisfactory also). Despite the heavy fecal inoculum on the plate a high per-

centage of pure cultures are obtained if the suspicious colony is touched only at its elevated center without "scooping."

Organisms "positive" for *Shigellae* on this medium are directly inoculated to three sugars, mannitol, xylose, and rhamnose. A needle is used and dipped in succession into the three tubes. The fermentation reaction after 24 hours' incubation differentiates organisms found in this country as follows:

	Mannitol	Xylose	Rhamnose
Flexner (including Boyd's 88)	+	—	—
Sonne	+	—	+
Schmitz	—	—	+
Alkalescens	+	+	—

Tube agglutination tests are also set up immediately using growth from the Kligler's slants. Three diagnostic sera are employed, polyvalent Flexner (including Boyd's 88), Sonne, and Schmitz. A supply adequate for several days is diluted to one or at most two dilutions below the titer of the anti-serum. One-half or 1 ml. of this is added to small test tubes. Using a needle, a small amount of growth from the slant is transferred to the tube and is readily brought into a smooth suspension. If the probable variety of the organism is known, only one tube is needed; if not, Flexner and Sonne are both used. Except in outbreaks, Schmitz anti-serum is employed only when indicated by the sugar reactions since this organism is rarely found in endemic cases. Positive agglutination tests may be recorded and reported after 2 to 4 hours in the water bath, but negative readings are delayed till the following morning. For examinations under the conditions stated these simplified tests reliably identify most suspicious organisms isolated. For the few which are neither clearly negative or positive more extensive cultural tests are used. Further procedures are re-

quired when other pathogens, as *Salmonellae*, may be involved.

Enteric bacteriology in the past was difficult, time consuming and often unproductive. That situation no longer holds true. Culturing for *Shigellae* is now one of the simpler laboratory procedures and these tests may be done in substantial numbers when needed, provided the laboratory is not far removed from the individuals to be examined.

THERAPY

Attention is limited in this study to the use of sulfonamides in shigellosis.

The following method has been used in evaluating the relative efficacy of different sulfonamides in *Shigella* infections. Cultures were obtained before treatment and at daily intervals after the beginning of medication. All were taken by rectal swabs and S. S. agar plates were inoculated immediately in a uniform manner. The number of clear suspicious colonies per plate was counted (or estimated) and representative types picked for identification. Medication was dispensed in individual boxes or envelopes bearing the patient's name and directions as to dosage. Treatment was continued until at least two consecutive daily cultures were negative. Post-treatment follow-up examinations were obtained. Control cases in adequate numbers were similarly followed. Blood counts and urine examinations were ordered twice weekly on some, not on all, to obtain evidence of any minor toxic reactions. Sulfonamide levels in the blood and in fluid feces (following saline laxative) were determined on series of cases receiving the different sulfonamides. Up to the present over 1,500 individuals known to be infected with *Shigellae* (Flexner, Sonne, or Schmitz) when treatment was started, have been studied. In all, ten sulfonamides were used. The major observations were these:

All sulfonamides had some influence

in cutting short the duration of these infections.

Flexner strains responded promptly (with very rare exceptions); Schmitz infection was slightly more resistant; while Sonne cases and carriers cleared least satisfactorily.

The poorly absorbed sulfonamides, though given in larger doses, had no demonstrable superiority in effectiveness in Flexner or Schmitz infections and the response was less satisfactory in one regard. The interval between the beginning of medication and a clinical or bacteriological response was longer with the poorly absorbed than with the absorbed preparations.

Sonne infections were more resistant to all sulfonamides. The best results were obtained with large doses of sulfasuxidine. All but a small percentage responded in a little longer time to the absorbed sulfonamides; the resistant cases were handled best by changing to sulfasuxidine.

Toxic reactions were rare (not observed with poorly absorbed sulfonamides) as would be expected with treatment usually terminating in 7 days or less.

Cases and carriers responded equally well to chemotherapy.

Concerning the choice of sulfonamides there need be no rigid rules. Sulfanilamide or sulfapyridine is not recommended. Other absorbed sulfonamides (sulfapyrazine, sulfadiazine, sulfamethazine, sulfamerazine, and sulfathizole) are acceptable. The first appears to have slightly superior properties, the last to be less effective. Among the poorly absorbed compounds, we regard sulfasuxidine as superior to sulfaguanidine and reserve judgment on "sulfathaladine."

We recommend, therefore, that the treatment of shigellosis (cases or carriers) begin with an absorbed sulfonamide. Follow-up cultures should be taken not later than the 4th and again

on the 6th day of treatment. If these or any subsequent two cultures are negative, the individual may be released. If they are positive, and particularly if the organism is "Sonne," a change to sulfasuxidine would be desirable. When cultures cannot be obtained, a treatment of 5 days for Flexner and Schmitz and of 7 days for Sonne is recommended.

A satisfactory dosage for adults for all absorbed sulfonamides is 1 gm.; of sulfaguanidine and sulfasuxidine 5 gm.; and of sulfathaladine 2.5 gm.; all four times daily. Double these amounts may be given as the initial dose. Children (between 25 and 75 lbs.) receive one-half the adult dosage; infants, 0.065 gm. of absorbed sulfonamide per lb. of body weight per day, and proportionately larger amounts of the poorly absorbed compounds. Amounts smaller than the above have been used and found effective in Flexner infections.

APPLICATIONS

The reliable diagnosis of communicable diseases on an etiological basis is an accepted objective in public health practice. The diagnosis of the diarrheal diseases is far below standard since the necessary bacteriological tests are infrequently employed. The simplification of the technic of fecal cultures makes it practicable to recommend that more laboratories and particularly the smaller clinical laboratories be encouraged to make this diagnostic procedure readily available. State health department laboratories would need to give leadership, instruction, and supervision. The agglutinating anti-sera also might be provided, and it could be agreed, if deemed advisable, that all suspicious positive cultures would be sent to the state laboratory for full identification.

The prompt institution of sulfonamide therapy in the young is required to prevent deaths and to speed recov-

ery. However, in older children and adults with the milder clinical disease, chemotherapy has its major importance as a control measure, where it is used to prevent and terminate carrier states.

Early diagnosis and specific therapy are of particular importance when the case is the initial infection in a susceptible group. Adequate attention to such cases and to their contacts is considered of major importance in the prevention of institutional outbreaks. Here we advocate the bacteriological diagnosis of all acute diarrheal disorders which continue for more than 24 hours, or which in the first 24 hours are accompanied by fever or other symptoms. If two or more cases occur within a week in a group having common living quarters, all members of that ward or dormitory should be cultured. Such a program is viewed as practicable when the tests can be done in the institution's own laboratory, or in another one nearby which can function as such.

Kuhns¹ has described a control program for an army service command in which, in addition to strict sanitary measures, he advocates the bacteriological diagnosis of all cases of diarrhea, and the treatment of positive cases and recognized carriers with sulfonamides. Presumably procedures may be modified to meet the varying needs of military medicine.

Though advocating methods designed to aid in the prevention of outbreaks, we recognize that assistance in control is usually requested after the outbreak is well established. Ordinarily on the first survey at least 10 per cent of the group are proved infected, and this percentage may reach 35 as was found in a military unit in Puerto Rico. Under this condition the following procedure has been used repeatedly with satisfactory results:

Infected individuals are identified through the immediate examination of all with symptoms and by cultural

TABLE 1

The Control of Outbreaks of Shigella Infection through the Use of Sulfonamides

Group	Average Population	Variety of Infection	Number of Infected Individuals Found on Cultural Surveys							
			Days Before Treatment				Day Treatment Started	Days Following Beginning of Treatment

F	70	Sonne	17	15	12	8	1

* Average of two surveys

surveys. All cases are treated with the onset of symptoms and all carriers on identification. Surveys are repeated usually about twice weekly. If practicable, infected individuals are isolated from the group and are treated with sulfonamides until discharged after two consecutive negative cultures. The group is regarded as free of significant infection when no positive individual is found on two successive surveys.

The results of such a program in a military unit have been described by Cornell, Watt, and Dammin.² Further illustrative findings are shown in Table 1 (Group A and B). Cases of dysentery began to occur in late March, 1943, among the inmates of two neighboring cottages in an institution for the mentally defective. Clinical cases only were treated at first, while both groups were followed by cultural surveys. From March 29 to April 13 all in Group A were examined 5 times. The prevalence of the infection was at a high level throughout. Then all individuals positive in any of the last three examinations and all additional positives revealed on subsequent surveys were placed on treatment. The prevalence rapidly fell to a low level as shown. However, the first entirely negative survey was on May 13. Group B was handled similarly. From April 4 to 22, clinical cases only were treated and there were five surveys with the

findings shown. During this period the prevalence declined moderately. However, after beginning the treatment of all individuals known to be infected, it dropped promptly to a low level. The last positive was found on the 6th day after this procedure was started. In the subsequent 4 weeks, all individuals were culturally negative in each of four surveys. In these and in other groups the occurrence of clinical disease was promptly prevented by this control measure. Also a high total prevalence was readily reduced to a low one, but it was frequently difficult and in some groups impossible to attain the goal of complete eradication of the infection.

A second approach to the control of established outbreaks is now under investigation and a progress note is offered. Here sulfonamides are used "prophylactically" or as it might better be described for "mass therapy" with minimal doses of the drug. Heavily infected groups, having a combined population of 1,646 have been observed. On this treatment, as with that described above, there was a prompt reduction to almost complete disappearance of clinical cases. The total prevalence of Flexner infections declined with striking rapidity as is illustrated by Groups C and D in Table 1. Sulfadiazine 1 gm. twice daily was used in the former, sulfapyrazine 0.5 gm. twice daily in the latter. The preva-

lence of Sonne infection under small dosage (1 gm. of poorly absorbed and 0.5 gm. of absorbed sulfonamide twice daily) declined more slowly, though the course of infection in the treated groups was modified favorably. Groups E and F treated with sulfadiazine and sulfa-pyrazine as above are illustrative. Risks are recognized in this "prophylactic" use of sulfonamides. Resistant strains might be developed which would tend to spread in spite of continued medication. Also, the immediate and remote effect of this dosage on the individual must be examined further. Thus the varied aspects of this simple approach to control require continued critical study.

These newer procedures cannot replace the established methods designed to prevent the spread of fecal pollution. We join in emphasizing the importance of sanitation and personal cleanliness. However, these additional supplementary methods of control are now available and are most applicable where diarrheal diseases are most troublesome, i.e., in institutional groups and military units. They can be used most simply and we believe most effectively in the prevention of outbreaks. The handling of widely distributed epidemics is more difficult because of the amount of laboratory work involved. Here the epidemiologist or administrator will need to evaluate the present and potential gravity of the outbreak and adjust control procedures accordingly.

CONCLUSIONS

1. The requirements for more effective control of *Shigella* infections in-

clude reliable diagnoses of mild as well as severe cases, a recognition of the rôle of carriers and more direct attention to the individuals infected.

2. The slow evolution of *Shigella* outbreaks provides the need and the opportunity for the application of control procedures.

3. Laboratory technics for the identification of *Shigellae* have been simplified and increased in reliability.

4. A free use of cultural tests for diagnostic purposes and for the identification of carriers is practicable.

5. Well absorbed sulfonamides, as well as poorly absorbed preparations are effective in *Shigella* infections, and are recommended.

6. Prompt diagnosis and immediate specific treatment of initial cases and early carriers is advocated for the prevention of outbreaks.

7. In the handling of established outbreaks, cases and carriers may be identified through diagnostic tests and cultural surveys and all discovered infected individuals treated till culturally free of *Shigellae*.

8. The merits of "mass therapy" with minimal doses of sulfonamides are not yet securely established.

9. These newer control procedures have a proper place among the methods now available for the prevention of *Shigella* infections, particularly among institutional inmates and in military units.

The Problem of Falsely Doubtful and Positive Reactions in the Serology of Syphilis*

JOHN A. KOLMER, M.D.

Professor of Medicine, Temple University, and Director of the Research Institute of Cutaneous Medicine, Philadelphia, Pa.

AT no time more than at present has the problem of falsely doubtful and positive reactions in the serology of syphilis commanded as much attention and importance. This is not only due to legally required serologic tests before marriage and during pregnancy, but to the testing of thousands upon thousands of selectees for the Army, Navy, and other services, as well as of thousands upon thousands of civilian donors of blood for the preparation of plasma.

However, while doubtful or positive reactions occurring in presumably non-syphilitic individuals are always very disturbing and place a heavy responsibility upon physicians in relation to their clinical interpretation, this present widespread employment of serologic tests for syphilis is not without the great advantage of discovering unsuspected cases of the disease. This in turn usually results in appropriate treatment which is not only of benefit to the individuals concerned, but to the public at large by way of reducing the chances of its transmission to others.

Following the discovery of the Wassermann or complement-fixation and various flocculation tests for syphi-

lis, falsely positive reactions were reported from time to time with practically all methods, not only in a large number of various non-syphilitic diseases of human beings but in presumably normal non-syphilitic individuals as well. But up to about fifteen years ago they were thought to be due largely to technical errors, except in the case of leprosy and malaria. Since then, however, and especially during the past eight years, the results of annual interstate serologic surveys conducted by the U. S. Public Health Service in coöperation with the American Society of Clinical Pathologists, have clearly shown that biologic falsely positive reactions may occur not only in a number of non-syphilitic diseases and conditions but in presumably normal non-syphilitic individuals as well. I refer especially to these serologic surveys because the Committee on Evaluation of Serodiagnostic Tests for Syphilis have not only selected syphilitic and presumably non-syphilitic donors with commendable care and skill, but because all specimens were submitted to various author-serologists themselves in whose laboratories it may be reasonably assumed that technical errors were reduced to a minimum. For these reasons, therefore, I have largely confined myself in this study to an analysis of the results reported by author-serologists and state laboratories in the

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

TABLE 1

*Sources of Technical Falsely Doubtful and Positive Serologic Reactions**(A) Due to Errors in Collection Resulting in Contamination or Hemolysis*

Bacterial contamination
 Chemical contamination from unclean containers
 Using oxalate or citrate
 Improper storage of specimens
 Delay in sending specimens to laboratory
 Mislabelling of specimens
 Post-mortem specimens

(B) Due to Errors in the Laboratory

Insufficient skill and experience
 Failure to follow technic exactly as described by author-serologists
 Mix-up of specimens
 Improperly prepared glassware
 Faulty reagents
 Inexact measurements
 Inadequate controls
 Improper reading of reactions
 Errors in recording and reporting reactions

nine serologic surveys begun in 1935, including the Washington serology conference held in 1941.

DOUBTFUL REACTIONS

While the committee has adopted the plan of penalizing laboratories one-half point for a doubtful reaction occurring in a presumably non-syphilitic individual and crediting one-half point for a doubtful reaction in the case of a syphilitic individual, in this study I have preferred to list doubtful reactions on the same basis as positive reactions, as was the policy of the committee in the first survey held in 1935. In practice at least it has been my experience that doubtful reactions occurring in presumably non-syphilitic individuals require almost as much consideration from the standpoint of clinical interpretation and management as weakly positive ones, and especially if repeatedly doubtful. Furthermore, while single doubtful reactions should never alone be the basis for the diagnosis of syphilis, neither should they be completely ignored because the disease is unexpected, and especially since they are sometimes the only evidence indicative of possible chronic latent syphilis, either congenital or acquired.

TECHNICAL FALSELY DOUBTFUL AND POSITIVE REACTIONS

Unfortunately there are many sources

for falsely doubtful and positive reactions due to technic. As summarized in Table 1, these may be divisible into those incident to the collection of blood resulting in excessive contamination or hemolysis, and thereby usually attributable to the physician himself, and those attributable to faulty technic in the laboratory. Certainly all serologic tests, regardless of their technical simplicity, require skill, experience, and scrupulous attention to all details regardless of how inconsequential they may appear. For this reason the Committee on the Evaluation of Serodiagnostic Tests for Syphilis has always placed proper emphasis on the advisability of technicians conducting the tests exactly as described by their author-serologists. And, needless to state, the incidence of technical falsely doubtful and positive reactions varies according to the skill with which the tests are conducted; consequently, no test can be better than the laboratory conducting it. Under the circumstances it is to be expected that the incidence of falsely doubtful and positive reactions due to errors in technic will increase under present conditions because of the large number of technicians with insufficient training and experience being rushed into serologic testing for syphilis.

But there is another angle to this subject which has not commanded as much attention as it deserves. I refer

to the possibility of technical errors being inherent in the test itself so that falsely doubtful and positive reactions may occur in the hands of skillful and experienced technicians and, indeed, in those of the author-serologist himself. As is well known, every serologic test now employed can be made so sensitive as to yield doubtful or positive reactions with the sera of normal non-syphilitic individuals. In the race for sensitivity in the detection of syphilis author-serologists may commit the error of making their tests too sensitive. For my own part, I always have been and continue to be dedicated to the principle that it is better to reduce technical sensitivity to the level of 100 per cent negative reactions with the sera of normal non-syphilitic individuals even though this inevitably means missing the serological detection of an occasional case of chronic latent syphilis. In other words, I believe that the serologic tests for syphilis should be made technically only as sensitive as is consistent with what may be termed "practical specificity" for syphilis.

Under the circumstances it is not at all easy to determine what percentage of falsely doubtful and positive reactions is due to errors in the collection of blood and the setting up of tests and that due to the tests themselves. But if it may be assumed that in the serologic surveys the tests conducted in the laboratories of author-serologists were set up exactly as they have been described, it is apparent, as shown in Table 2, that under such conditions only one of the ten tests now commonly employed has had, up to the present time, 100 per cent negative reactions in all of the nine serologic surveys with the sera of normal, presumably non-syphilitic, individuals. In this connection, however, I point with pride to the fact that in the 1943 serologic survey all of the author-serologists listed in Table 2 reported 100 per cent negative reac-

tions with the sera of normal, presumably non-syphilitic, individuals.

* 1935, 1936, 1937, 1938, 1939, 1941, 1942, 1943, and Washington serology conference of 1941

In Tables 3 and 4 it is shown that technical errors alone, apart from those inherent in various complement-fixation and flocculation tests themselves, have apparently occurred in seven of the serologic surveys in a disturbingly large number of state laboratories. Thanks to the excellent efforts of the Committee on the Evaluation of the Serodiagnostic Tests for Syphilis, however, the situation in the last survey (1943) was greatly improved over that of the first, conducted in 1936. For example, in 1935, 50 per cent of state laboratories reported falsely doubtful and positive reactions with various complement-fixation tests, but only 13.4 per cent in 1943 (Table 3). Furthermore, the percentage of these reactions has dropped from between 1.0 and 10.0 per cent in 1936, to between 0.7 and 0.8 per cent in 1943. Somewhat less but nevertheless definite improvement has been observed also in the case of the various flocculation tests (Table 4). Thus, while 67.9 per cent of laboratories reported falsely doubtful and positive reactions in 1936, only 29.7 per cent reported them in 1943. And while the incidence of these reactions varied from 1.0 to 40.0 per cent in 1936, it

1943	74	52	70.3	22	29.7	0.8 to 16.8

dropped to between 0.8 and 16.8 per cent in 1943.

Under the circumstances it is apparent that there is still much room for improvement on the part of some state laboratories if it is assumed that the performance of tests in the laboratories of the author-serologists (Table 2) is acceptable as a measure of the incidence of falsely doubtful and positive reactions with the sera of normal, presumably non-syphilitic, individuals. Fortunately, many state laboratories are conducting serologic surveys themselves as a check on the performance of municipal, hospital, and private laboratories within their confines. I have not sufficient data bearing upon the results observed, but I hazard the opinion that not a few are below the performance of the state laboratories themselves although these intrastate surveys are gradually and progressively improving

the situation in a manner analogous to the annual interstate surveys conducted by the Committee on the Evaluation of the Serodiagnostic Tests for Syphilis.

BIOLOGICAL FALSELY DOUBTFUL AND POSITIVE REACTIONS IN NORMAL NON-SYPHILITIC INDIVIDUALS

Biological falsely doubtful and positive reactions are so designated because they are due to the presence of a reagin-like or other substance in the serum (shortly to be discussed), and therefore likely to occur in tests correctly conducted with skill and experience. That this substance may occur in the sera of normal non-syphilitic individuals cannot be denied but the true incidence is still unknown. In 1941 Eagle¹ estimated that with present-day serologic tests the incidence among university students was about 1 for every 4,000 persons tested, and perhaps even less. Mohr and his

colleagues² have recently reported 9 normal persons yielding these biologic nonspecific positive reactions.

As previously stated, falsely doubtful and positive reactions with the sera of normal persons may be and doubtless are due in the great majority of instances to technical factors incident to the conduct of the tests or inherent in them. For this reason it is not at all easy to differentiate between those falsely doubtful and positive reactions due to technical factors and those due to the biological factor. In so far as practising physicians are concerned, however, the important matter is the incidence of falsely doubtful and positive reactions due to a summation of these causes. In the 1943 serologic survey about 131 sera were supplied by the committee from normal, presumably non-syphilitic, donors. As previously stated, all of the author-serologists listed in Table 5 reported negative reac-

tion and probably all of these falsely doubtful and positive reactions in such a small series of sera were due to technical factors, but the results are sufficient for indicating what physicians may be warned to expect with the serologic tests now commonly employed under what may be regarded as average conditions.

Much less can be stated in regard to falsely doubtful and positive reactions with the cerebrospinal fluids of non-syphilitic individuals. For various reasons it has not been possible for the Committee on the Evaluation of Serodiagnostic Tests for Syphilis to supply them for the annual interstate serologic surveys. In so far as tests conducted by author-serologists themselves are concerned, however, data are available from the 1935 survey and the Washington serology conference held in 1941. These, as summarized in Table 6, indicate that cerebrospinal fluids are much

tions. The same was true of many of the state laboratories participating in the survey but, on the other hand, a few of the latter reported all the way from one doubtful or positive reaction per 100 individuals to as high as one per 6 in the case of a supersensitive flocculation test. I mention these facts because the performance of state laboratories is probably acceptable as a broad and general index of that of laboratories in general. Undoubtedly the great ma-

less likely than sera to yield these reactions. Undoubtedly this is due in large part to technical conditions but, on the other hand, it is quite likely that the reagin-like substance that may occur in the sera of normal non-syphilitic individuals yielding falsely doubtful and positive reactions does not occur in the cerebrospinal fluids of normal individuals. At least it is well known that natural antibodies occurring in the sera of normal individuals do not occur in

their cerebrospinal fluids, to which further reference will be made in relation to antibody for spirochetes in normal and syphilitic individuals.

* Based on the 1935 serologic survey and the 1941 Washington serology conference

BIOLOGICAL FALSELY DOUBTFUL AND POSITIVE REACTIONS IN DISEASE AND OTHER CONDITIONS

As previously stated, falsely doubtful and positive reactions with the various serum tests for syphilis have been reported from time to time in a very large number of various diseases and conditions. No useful purpose is served by reviewing the very extensive literature on the subject and particularly the early literature. But even in

the case of present-day methods it is difficult to draw hard and fast deductions, largely because of the practical certainty that many of the nonspecific reactions reported have been due to technical factors. Furthermore, with the possible exception of leprosy, it is more or less characteristic of the diseases yielding biologic nonspecific reactions that the true incidence of falsely doubtful or positive reactions may not be elicited by single examinations, especially since they tend to be evanescent and disappear within relatively short periods of time following recovery.

But that falsely doubtful and positive reactions may be due to the presence in sera of a reagin-like or other substance in some diseases, and particularly those due to infections, is now well proved. In Table 7, I have divided these into three groups including a large number in which the evidence is not by any means conclusive at the present time. In this connection it would appear, however, that yaws and pinta may be excluded from the category of biological nonspecific reactions, as the phrase is ordinarily interpreted, because both diseases are due to treponemas either so closely related to *Trepanema pallidum*

TABLE 7

Diseases and Conditions Known or Suspected of Causing Biological Falsely Doubtful and Doubtful Reactions

Group A Variable Incidence	Group B Incidence Unknown	Group C Evidence Not Conclusive
Yaws	Febrile diseases	Rheumatic fever

* Single examinations

As shown in Table 8, the incidence of doubtful and positive reactions in leprosy as based upon single examinations by author-serologists in the 1935 and 1941 Washington serology surveys, has varied from 38 to 68.2 per cent while the incidence in malaria has varied from 21.3 to 50 per cent. In malaria, however, Kitchen, Webb, and Kupper¹⁹ have reported that serially repeated tests show that 90 to 100 per cent of patients at some time in the course of the disease give biologic falsely positive Wassermann and Kahn reactions.

Since Barnard²⁰ first reported biologic falsely positive reactions occurring in an individual with vaccinia, the series of cases reported by Lynch and his colleagues⁷ and Favorite⁸ have together shown an incidence of doubtful and positive reactions varying from 3.9 to 12.3 per cent (Table 8) with the probability that the incidence is higher in flocculation than in complement-fixation tests. In this connection Major Charles R. Rein, Chief of the Division of Serology of the Army Medical School, informs me²¹ that 26, or 60

during the second week following vaccination and, with one exception, disappeared within 3 months. Of 28 additional individuals developing immediate or immunity reactions, only 2 showed doubtful or positive reactions. Incidentally, Major Rein also states that very few, if any, soldiers, showed doubtful or positive reactions ascribable to vaccination against tetanus or typhoid fever.

Curiously enough, however, while it is definitely proved that vaccinia and vaccinoid may produce temporary falsely doubtful or positive reactions in human beings, this may not occur in experimental vaccinia of rabbits. At least Miss Rule and I have observed negative Kahn, Kline, and Kolmer reactions in all of a small group comprising 12 normal rabbits with vaccinia in tests conducted 4 days, 1, 2, 3, and 4 weeks after the development of vaccinal lesions of the abdominal skin. All of the animals were selected on the basis of two preliminary negative Kahn, Kline, and Kolmer reactions before inoculation with highly virulent virus, all of the Kolmer tests being conducted

by the modification of my test²² for avoiding the nonspecific reactions shown by a large percentage of normal rabbits.

It would also appear that pulmonary tuberculosis, especially active febrile cases (Table 8), may show a very low incidence of falsely doubtful or positive reactions^{4, 5, 6} as may likewise be true of other febrile diseases^{4, 5} and especially the acute exanthemata. Here again, however, Miss Rule and I have ob-

reactions occurring in atypical pneumonias, and especially those due to viruses. Major Rein states²¹ that 10 cases in 50 have shown them after the 12th day of the disease, the majority disappearing or reacting negatively in 2 to 6 months.

In afebrile diseases, obstructive jaundice, malignant tumors, menstruation and pregnancy, however, the incidence of falsely doubtful and positive reac-

* Single examinations

† Convalescent pneumonia, diseases of gastrointestinal tract, diabetes, cardiovascular disease, postoperative convalescence and fractures

‡ Malignant neoplastic disease

served no confirmatory evidence in our experiments with a small number of rabbits. For example, 12 normal animals were selected on the basis of two preliminary negative Kahn, Kline, and Kolmer reactions. Four were inoculated intradermally (abdominal) with a virulent broth culture of Type I pneumococcus, 4 with a virulent culture of group A hemolytic streptococcus, and 4 with a virulent culture of *Staphylococcus aureus*. Within 48 hours all developed large lesions and fever, 4 succumbing with septicemia (positive heart blood cultures) in 3 to 7 days after inoculation. Kahn, Kline, and Kolmer tests conducted with the sera of surviving animals 4 days, 1, 2, 3, and 4 weeks after inoculation gave consistently negative reactions in all.

However, special mention should be made of falsely doubtful and positive

tions (Table 9) is apparently so nearly the same as may be expected from technical factors that I believe it may be properly stated that these diseases and conditions do not yield biologic non-specific reactions.

Unfortunately infectious mononucleosis has not been subjected to study in the serologic surveys. Furthermore, the literature is quite contradictory and confusing and fails to indicate the true incidence of falsely doubtful and positive reactions in this disease because it is based so largely upon single examinations. Thus, as shown in Table 10, the incidence of reactions reported by various investigators has varied all the way from none to 100 per cent, with an average of 7.3 per cent doubtful or positive complement-fixation reactions in 202 cases and 9.6 per cent doubtful or positive flocculation reactions in 157 cases.

SEROLOGIC INDICES

While it is not my purpose to discuss at length the present-day serologic tests from the standpoint of sensitivity in the serum diagnosis of syphilis, the subject may be referred to briefly. In Table 11 has been summarized the doubtful and positive reactions reported by author-serologists in the nine serologic surveys, including the Washington serology conference, as indicative of what may be expected under optimum conditions with the tests listed. It will be observed that the incidence for all cases of syphilis, treated and untreated, has varied from 77.6 to 90.9 per cent. But in evaluating the various tests due consideration must be given the incidence of falsely doubtful and positive reactions.

I have sought to do this in each test by subtracting from the percentage of reactions observed in syphilis (Table 11) the percentage observed in presumably normal non-syphilitic individuals (Table 2) multiplied by 10, as suggested by Herman Brown. The results are what I have termed the "serologic indices" shown in Table 11. On this basis the present-day serologic tests listed in the table show indices varying from 66.5 to 84.5 per cent. Needless to state, it is not reasonable to expect that any serologic test can be made sufficiently sensitive to yield positive reactions in all cases of syphilis under conditions whereby the incidence of falsely doubtful and positive reactions are kept at their present very low

TABLE 11

*Doubtful and Positive Reactions Reported by Author-Serologists with the Sera of Syphilitic Individuals in the Serologic Surveys **

Tests	Total Sera Tested	Doubtful and Positive		Serologic Indices
		No. Sera	Per cent	
Eagle Wassermann	1,678	1,302	77.6	77.6 — (0.6 × 10) = 71.6
Eagle macroflocc.	1,880	1,544	82.1	82.1 — (1.4 × 10) = 68.1
Eagle microfloc.	1,104	944	85.5	85.5 — (1.9 × 10) = 66.5
Hinton regular	2,281	1,941	85.1	85.1 — (0.5 × 10) = 80.1
Kahn presumpt.	1,855	1,559	84.0	84.0 — (0.3 × 10) = 81.0
Kahn stand.	2,083	1,647	79.1	79.1 — (0.2 × 10) = 77.1
Kline diag.	2,295	1,860	81.0	81.0 — (0.4 × 10) = 77.0
Kline exclusive	1,489	1,353	90.9	90.9 — (1.0 × 10) = 80.9
Kolmer	2,276	1,790	78.6	78.6 — (0.0 × 10) = 78.6
Mazzini flocc.	835	722	86.5	86.5 — (0.2 × 10) = 84.5

* 1935-1943 including the Washington serology conference

and gratifying levels. For example, time is required for the production of reagin in primary syphilis, and its production in chronic latent syphilis may be so slight as to escape serological detection. Undoubtedly, however, further serologic research will improve sensitivity, especially in the way of producing superior antigens, but this is only to be welcomed in case the incidence of nonspecific reactions due to *technic* is kept at or very near zero. It may be, however, that any material increase in sensitivity for syphilis will also increase the incidence of biologic nonspecific reactions in normal individuals and those with non-syphilitic diseases.

SPIROCHETAL COMPLEMENT-FIXATION TEST

While the pioneer investigations on complement-fixation in syphilis employing antigens prepared of cultures of alleged *Treponema pallidum* were conducted in this country about thirty years ago by Noguchi,²³ Craig and Nichols²⁴ and Kolmer, Williams, and Laubaugh,²⁵ the subject never attracted much attention until 1929 when Gaetgens and Otto²⁶ greatly renewed interest in it by reporting that a phenolized saline suspension of cultures of the Reiter strain of alleged *T. pallidum* as antigen, commercially available in Germany under the name of "Palligen" yielded specific complement-fixation reactions in syphilis which were apparently separate and independent of the Wassermann and flocculation reactions as well as more sensitive than the latter, especially in treated syphilis. I have elsewhere summarized the literature on the subject,²⁷ but here it may be stated that of a total of 13,636 tests conducted with "palligen" and the sera of syphilitic individuals, the incidence of positive reactions has varied from 44.5 to 100 per cent, with an incidence of positive Wassermann reactions varying from 30.4 to 100

per cent. In a total of 36,255 tests conducted with "palligen" and the sera of presumably non-syphilitic individuals the incidence of falsely positive reactions has varied from 0 to 3.4 per cent, with an incidence of 0 to 2.7 per cent in the case of the Wassermann reaction.

In the Washington serology conference⁵ complement-fixation tests were conducted by Dr. Eagle with a spirochetal antigen prepared of cultures of the Reiter strain. Carola E. Richter of the Pennsylvania State Department of Health Laboratories, who kindly substituted for me at the conference, also conducted the Kolmer complement-fixation test with an antigen prepared of cultures of the same strain by Clara Kast. The results observed with both tests, as well as in duplicate tests employing the Eagle and Kolmer tissue or lipoidal antigens, are summarized in Table 12.

It will be observed that the two spirochetal complement-fixation tests yielded from 0.6 to 2.9 per cent falsely doubtful and positive reactions with the sera of normal individuals. In the Kolmer tests this percentage was not as high as previously reported²⁸ because the antigen was used in a smaller amount, but Kolmer and his colleagues^{27 28} have ascribed them to the presence of natural spirochetal antibody in human sera which is apparently of a group character, as similar reactions have been observed with antigens prepared of cultures of *T. microdentium* and *T. macrodentium*.²⁸ As expected, no falsely doubtful or positive reactions were observed with either test in the examination of cerebrospinal fluids from 107 presumably normal individuals and non-syphilitic individuals afflicted with neurologic or mental diseases, because natural antibodies do not ordinarily occur in normal spinal fluids. But it is evident, as shown in Table 12, that this spirochetal antibody is increased not only in syphilitic but in non-syphilitic

TABLE 12

Percentages of Doubtful and Positive Reactions in Complement-Fixation Tests Employing Tissue and Spirochetal Antigens *

Clinical Status	Total Sera Tested	Eagle Tests		Kolmer Tests	
		Tissue Antigen	Spiro. Antigen	Tissue Antigen	Spiro. Antigen
Normal individuals	169	0.0	0.6	0.0	2.9
Afebrile diseases or conditions	130	0.0	2.3	0.8	6.2
Intercurrent febrile diseases	46	0.0	4.4	2.2	10.9
Tuberculosis (any type)	59	0.0	3.4	0.0	6.6
Malignant disease	49	0.0	8.1	0.0	20.4
Leprosy in any stage	60	45.7	24.1	61.0	28.8
Malaria (febrile and afebrile)	12	25.0	25.0	54.5	27.3
Early syphilis (prim. and sec.)	45	84.1	88.8	91.1	84.4
Syphilis, less than 4 yrs.	119	49.5	61.3	60.5	59.6
Syphilis, over 4 yrs.	212	68.3	90.0	80.0	80.5

* Based upon the results reported at the Washington serology conference

individuals as well with febrile and afebrile intercurrent diseases, tuberculosis, malignant disease, leprosy, and malaria. Under the circumstances it is also evident that the spirochetal complement-fixation test is of no value in differentiating between true and falsely doubtful and positive reactions in so far as serum tests are concerned. It may be otherwise, however, in the case of tests employing cerebrospinal fluid, not only because falsely doubtful and positive reactions apparently do not occur in normal individuals in tests employing spirochetal antigens, but because both Eagle and Kolmer reported about 85 per cent doubtful and positive reactions in 127 treated and untreated cases of syphilis of the central nervous system. Under the circumstances a positive spirochetal complement-fixation reaction with spinal fluid in a doubtful case of syphilis may be of value in establishing the presence of the disease, although a negative reaction is of no value in excluding the possibility of its presence. In this connection it is also to be stated that Kolmer, Kast, and Lynch²⁰ found that antigens prepared of virulent *T. pallidum* (Nichols-Hough strain) obtained from acute testicular syphilomas of rabbits, were more sensitive and specific than antigens prepared of cultures of alleged *T. pallidum*, but owing to

technical difficulties in their preparation they probably cannot be employed.

Undoubtedly, therefore, antibody for *T. pallidum* is produced in syphilis and presumably likewise in yaws and pinta. This is based not only upon complement-fixation but upon agglutination tests as well in so far as syphilis is concerned.²⁰ Why an increase of spirochetal complement-fixing antibody occurs in leprosy, malaria, tuberculosis, and other diseases listed in Table 11 is difficult to state. It may be assumed that the plasmodia of malaria and the bacillus of leprosy share with *T. pallidum* a common antigenic substance responsible for its production. But unless or until proved otherwise, I prefer to assume that in these non-syphilitic diseases it is due to increase of the natural group spirochetal antibody in the nature of an anamnestic reaction.

MECHANISM OF FALSELY DOUBTFUL AND POSITIVE REACTIONS

Little of a definite nature is known of the mechanism of complement-fixation and flocculation reactions in syphilis employing alcoholic extracts of beef heart or other mammalian tissues as antigens. This is very unfortunate because precise knowledge is so important in relation to the solution of the problem of falsely doubtful and positive

reactions. I believe it may be stated, however, that the mechanism is fundamentally the same in each procedure. At least it appears that both are due to the presence in serum and spinal fluid of a substance capable of flocculating the alcohol-soluble tissue lipoids in colloidal suspension. In complement-fixation tests these flocculi cannot be seen with the naked eye, but are capable of absorbing or fixing complement. But under proper technical conditions the flocculi can be rendered grossly visible, as in the macroscopic flocculation tests, or, microscopically visible by ordinary examinations, as in the microscopic flocculation tests.

The important question concerns the nature of this flocculating substance. This applies not only to syphilitic human beings but also to normal persons and non-syphilitic individuals with other diseases; also to normal rabbits, cattle, horses, mules, chickens, and other lower animals which are well known to yield biological falsely doubtful and positive complement-fixation and flocculation reactions. It is commonly regarded as an antibody or antibody-like substance known as reagin.

In the light of our present knowledge, however, it seems to me that this substance is not an antibody and quite separate and apart from the spirochetal antibody previously discussed. Rather it appears that it may be a modified serum globulin which may not be detected by ordinary chemical methods, although Cardon and his colleagues³⁴ have suggested recently that hyperproteinemia, and especially hyperglobulinemia, may be in relation to the mechanism of biologic nonspecific reactions. At least various investigators³¹⁻³⁴ have shown that practically all sera of normal persons contain a substance capable of flocculating tissue lipoids under suitable technical conditions. Under the circumstances it appears that the difference between non-

syphilitic and syphilitic sera is one of degree rather than of kind—quantitative rather than qualitative.³¹ In syphilis, yaws, and pinta it may be that the reacting substance is only an increase of this factor, although I believe that it may be a globulin or a modified globulin which, as previously stated, may not always be detected by the usual chemical methods now employed. If this is true, one may readily understand that an increase of a normal globulin or its modification may account for positive complement-fixation and flocculation reactions not only in syphilis, yaws, and pinta, but in an occasional normal person as well as in non-syphilitic individuals with leprosy, malaria, vaccinia, infectious mononucleosis, virus pneumonia, etc.

I have elsewhere discussed this subject with more detail²⁷ but here it may be stated that the preponderance of evidence at the present time is in favor of regarding the reagin as separate and distinct from the spirochetal antibody. Gaetgens³⁵ as well as Kroó, Schultze, and Zander³⁶ have expressed this opinion while Beck,³⁷ Kolmer, Kast, and Lynch³⁸ have come to this conclusion largely on the basis of absorption tests with syphilitic sera with tissue lipoids for the removal of the reagin and with spirochetes for the removal of the spirochetal antibody. Eagle and Hogan,³⁹ however, have stated on the basis of their absorption experiments, that the lipodotropic reagin and spirochetal antibody are identical, or, in other words, that positive complement-fixation and flocculation reactions with tissue antigens as well as positive spirochetal complement-fixation reactions are due to spirochetal antibodies.

Be this as it may, the important practical question is whether or not the reagin responsible for biological nonspecific reactions with the sera of human beings and the lower animals is different in its properties from the reagin

responsible for complement-fixation and flocculation reactions in syphilis, yaws, and pinta. Kahn⁴⁰ believes that the former is most active in flocculation tests conducted at a cold temperature (1° C.) and when the salt concentration of the reacting system is reduced to a minimum, while the latter is most active at body temperature. On this basis he has devised various "verification tests" for differentiating between biological nonspecific and specific reactions to which further reference will be made. Here it may be stated, however, that in the Kolmer complement-fixation test, at least, there can be no doubt of the fact that the reagin produces much more complement-fixation at a cold temperature of 4 to 8° C. over a period of 15 to 18 hours than in a water bath at 38° C. for 1 hour, regardless of whether it is occurring in the normal sera of human beings or the lower animals, in the sera of non-syphilitic human beings with various diseases and conditions, or in the sera of syphilitic human beings. In other words, differentiation between biological nonspecific and specific reactions has not been found possible on the basis of the temperature employed in conducting the tests in so far as complement-fixation is concerned.

Personally, however, I am not without hope that a solution of the problem will be found by changing the methods employed in the preparation of tissue antigens. Investigations now being conducted by Herman Brown and the writer indicate that it may be possible to remove certain lipoids with which the nonspecific reagin reacts without reducing the sensitivity of the antigen in relation to the syphilis reagin. Furthermore, if it is found possible to prepare antigens which are satisfactory for the serodiagnosis of syphilis without the addition of a sensitizing sterol, like cholesterol, an additional step toward a solution of the problem will have been

accomplished, and I am not without hope that this is possible.

MANAGEMENT OF FALSELY DOUBTFUL AND POSITIVE REACTIONS

While these matters are being ironed out by present and future serological investigations, however, the management of falsely doubtful and positive reactions occurring under present conditions constitutes a practical problem of first rate importance in order to reduce to a minimum the regrettable error of the needless treatment for syphilis. To this end the close coöperation of clinicians and serologists is required. Even though the incidence of nonspecific reactions due to technic is very low, when present-day approved tests are correctly conducted, and even though false reactions with the sera of normal, presumably non-syphilitic, individuals may occur only once in anywhere from 1,000 to 4,000 examinations, yet all figures and statistics are of little avail in so far as the individual involved is concerned.

As summarized in Table 13, certain clinical procedures are indicated. It is a mistake for the physician to place the whole burden on the laboratory. Certainly no director of a laboratory, serologist or technician who is completely ignorant of the clinical status of the individual and the conditions surrounding the collection, labelling, and delivery of the specimen, can make so important a decision as to whether syphilis is or is not present, whether treatment should or should not be given or, in the case of the latter, the kind and duration of treatment to be administered. In other words, the serologic tests alone are insufficient and do not constitute a short-cut or royal road in differentiation between true and false doubtful and positive reactions. As a matter of fact, the difficulty in the interpretation and management of presumably nonspecific reactions is in

TABLE 13

Clinical Procedures in the Interpretation and Management of Presumably Falsely Doubtful and Positive Reactions

1. Collect and deliver specimens with due care against bacterial and chemical contamination to avoid technical nonspecific reactions (see Table 1).
2. A negative history for syphilis is of little or no value in excluding the possible presence of the disease.
3. Make thorough examinations for acquired and congenital syphilis.
4. Take careful history and make necessary examinations if and when necessary for the diseases and conditions capable of yielding biological nonspecific reactions (see Table 7).
5. Examine spinal fluid in selected cases. Positive results are indicative of syphilis. Negative results do not exclude its possible presence.
6. Provocative treatment may be tried in some cases but negative serologic results do not exclude the possibility of syphilis.

relation to the clinical skill and experience of the physician in chronic acquired and especially late congenital syphilis. There is no substitute for thorough clinical examinations so skillfully indicated and outlined by Stokes and Ingraham⁴¹ and by Moore and his colleagues.⁴²

On the other hand, however, serologists and technicians cannot escape participation and a heavy responsibility in the elucidation of the problem in individual cases as I have attempted to summarize in Table 14. Certainly there is no one best test for syphilis. Serological diagnosis is always best served by using two or more approved methods routinely of which, in my opinion, one at least should be a complement-fixation procedure. Needless to state, this is not always possible when very large numbers of tests are to be conducted, as in state and other laboratories. Under such conditions a screen test of acceptable sensitivity and speci-

ficity is required, of which my preference is for one of the micro-flocculation procedures. But I believe that all positive reactions should be checked by another method before a report is rendered. Under these conditions it is inevitable that a screen test may occasionally give a falsely negative reaction, but unless conditions permit the routine use of two or more methods it is about the best that a hard worked laboratory can do. In my own laboratory all sera are tested routinely by a complement fixation, a macro-flocculation and a microflocculation procedure.

As previously stated, physicians should never jump to the conclusion that syphilis is present on the basis of a single doubtful or positive reaction unless there is supporting historical or clinical evidence. But, on the other hand, they should not be ignored simply because clinically unsuspected. When such reactions are suspected of

TABLE 14

Serological Procedures in the Interpretation and Management of Presumably Falsely Doubtful and Positive Reactions

1. Conduct the test or tests with care and skill exactly as described by author-serologists to avoid technical nonspecific reactions as much as possible (see Table 1).
2. Conduct the tests by several methods in the same or different laboratories.
3. Spirochetal complement-fixation reactions with sera are of no value but positive reactions with spinal fluids are indicative of syphilis; negative reactions do not exclude its possible presence.
4. The value of verification tests is uncertain but they are worthy of trial.
5. Withhold judgment and treatment but repeat the tests at intervals over a period of at least 3 to 6 months. If negative reactions occur syphilis is usually to be excluded; if positive reactions persist syphilis is probably present and treatment is advisable.

being nonspecific, judgment and treatment should be withheld for at least 3 to 6 months, with a repetition of the tests every 2 to 4 weeks. If, during that time, the reactions have become repeatedly negative and there are no historical or clinical evidences of syphilis, it would appear that the disease may be excluded. However, if persistently positive reactions are observed with approved methods properly conducted, even though but weakly positive, I see no escape from the advisability of making a tentative diagnosis of syphilis and instituting treatment in the best interests of the individual involved.

Discussion

JOHN F. MAHONEY, M.D., F.A.P.H.A.

*Director, Venereal Disease Research Laboratory, U. S. Marine Hospital,
Stapleton, S. I., N. Y.*

THE concluding paragraph of Dr. Kolmer's paper conveys a thought which may well deserve further emphasis, especially in regard to the transposition of test findings into terms of clinical syphilis. Almost from the time of the development of the Wassermann test a positive finding has been accorded a diagnostic weight amounting almost to infallibility. As the newer tests were developed and came into use they were permitted to share in this position of reliability. As the use of the tests became more general and as the multiple testing of individual sera was practised, the vagaries and discrepancies of test findings became apparent in treated syphilis as well as in conditions without syphilis as a causative factor.

At the present time, and assuming that the methods which are available are carried out in an acceptable manner, the advisability of exercising a careful scrutiny of all factors involved, before permitting the diagnosis of syphilis to be based entirely upon serologic findings, is accepted. This is important especially when clinical and historical confirmations are lacking. The waiting period, referred to by Dr. Kolmer, during which the diagnosis is withheld al-

though positive test findings may have been recorded, serves as a safeguard in instances in which such conditions as infectious mononucleosis, virus pneumonia, vaccinia, or any of a host of other intercurrent factors may be responsible for the positivity expressed by one or a group of well conducted tests. A time interval of several months before making an arbitrary diagnosis is sometimes sufficient for the reacting substance to disappear entirely from the blood serum or to have been reduced in concentration to a point that the decline in strength of the reaction is obvious.

The use of the waiting period is of limited helpfulness in instances of false positive or discrepant findings occurring in pregnancy. Here it becomes necessary to take into account the risk of an unfavorable outcome as regards the child. This consideration sometimes dictates that the patient be placed under treatment without appreciable delay and without too much regard for the refinements of diagnosis. An attempt to establish the true syphilis status of the mother should be made after delivery although the interposition of treatment always complicates the diagnostic problem.

It is felt that the practice of reporting test results as positive, doubtful, or negative makes impossible the best usefulness of serodiagnostic tests in instances of biologic false positive reactions. A positive report may be given to a reaction which is just sufficient to be so classified or it may represent a concentration of reacting substance manyfold that required to produce the minimal reaction. The authenticity of

the minimal reaction may well be questioned in instances in which there is lack of confirmation by history or clinical findings. A persistent positive reaction of high titer is, in the majority of instances, the product of syphilis. The information which would permit the diagnostician to make a discrimination of this kind is lost through the practice of withholding the numerical reading of the degree of positivity.

Hard of Hearing Appointments

The American Society for the Hard of Hearing, Washington, has announced the appointment of Raymond H. Greenman, as Managing Director of the Society. Mr. Greenman succeeds Betty C. Wright, who is on leave to serve with the American Red Cross as consultant in Army hospitals for the care

of deafened soldiers. Miss Wright will return to the Society as Director of Field Service. Mr. Greenman leaves a war assignment with the American Social Hygiene Association and was formerly Executive Secretary of the Tuberculosis and Health Association of Rochester and Monroe County, N. Y.

A NEW SERUM FOR A NEW PURPOSE

OUR older public health workers will recall ancient controversies between adherents of the "humoral theory" of immunity based on the work of Pasteur and the "cellular theory" suggested by the studies of Mechnikov. This apparent conflict has disappeared, with recognition of the fact that substances present in the blood stream must obviously be produced in living cells somewhere in the body; and the work of Besredka and Kahn has emphasized the fact that protective substances are often actually highly concentrated in particular body tissues such as the skin and the peritoneum.

Almost all of our previous researches have, however, been concerned with antibodies produced in response to the stimulus of materials derived from foreign protein or protein-like substances and specifically protective against such alien substances. In other words, they have been concerned with the sort of phenomena which can be classed as manifestations of specific immunity.

Within the past few years, a group of Russian biologists have opened up an entirely new area of research, based on evidence that the injection of material from the human body itself can stimulate the reticular system to a state of higher activity, which manifests itself in enhanced power to combat disease. This is a phenomenon of increased vital resistance against various maladies, rather than a specific immunity against any single foreign protein; and is related to the activity of connective tissue—a tissue which is conceived, not as primarily a mechanical framework of the body, but as a system of primary importance in the regulation of nutrition and metabolism. We may some day say that a man is as old as his connective tissue—rather than as old as his arteries.

The procedure developed by A. A. Bogomolets and his associates at the Institute for Experimental Biology and Pathology of Kiev¹ involves the production of an "Anti-Reticular Cytotoxic Serum" by the injection of horses with the cellular material from human spleen and bone marrow; and interesting methods of titrating the resultant horse serum have been devised by complement-fixation and in other ways. The Russian experiments suggest that this serum: (a) stimulates the production of hemolysins and agglutinins and the process of phagocytosis

(in a general rather than a specific sense) and is of value in puerperal and other infections; (b) aids materially in the treatment of war wounds and other surgical conditions and of frost-bite; (c) produces definite lowering of abnormal blood pressures; (d) in animals, checks the development of malignant growths. In the latter case, and perhaps under other conditions, excessive amounts of the serum produce a definitely unfavorable effect, so that dosage is of primary importance.

All this is, in high degree, startling and revolutionary; but the evidence presented is comprehensive and highly suggestive. This may prove to be one of the most far-reaching of the many interesting discoveries which have come to us from the great institutes of scientific research of the Soviet Union.

FLUORINE AND DENTAL CARIES

IT was nearly thirty years ago that Black and McKay demonstrated the relation of an excess of fluorine in drinking water to mottled enamel; and later researches showed that the presence of over 1.5 p.p.m. of fluorine in a public water supply was definitely associated with the presence of this particular dental condition.

In 1938, Dean, of the U. S. Public Health Service, noted that, among school children, in areas supplied with drinking water of high fluorine content and in which mottled enamel was endemic, incidence of dental caries was noticeably low. The relationship thus suggested was confirmed by chemical studies of the fluorine content of carious and non-carious teeth and by animal experimentation. It seems clear that we have, in this case, an intriguing example of the desirability of maintaining in the human body an optimal concentration of a particular chemical element—a value below this optimum tending to favor one diseased condition and a value above this optimum to cause another disease of a different type. It is possible that data with regard to fluorine content of water and food may explain in part the remarkable freedom from dental caries of certain primitive peoples and the alleged differences in this disease in first and second generation immigrants in this country.

In view of the extensive incidence of dental caries and of the baffling obscurity which has shrouded its causation, these discoveries are of primary importance; and the symposium presented on this subject was one of the highlights of the last A.P.H.A. meeting.¹

The possibility of controlling the development of dental caries by increasing the fluorine-content of public water supplies deficient in this element is obviously suggested; and Faust and other engineers have pointed out the practicability and economy of such a procedure. It would appear from the extensive studies of the U. S. Public Health Service that a 50 per cent reduction in the incidence of dental caries could be anticipated.

The addition of fluorine to water supplies would, however, chiefly affect the population of the future, since the process is fully effective only on individuals supplied with fluorine during the first eight years of life; and it could obviously influence only those persons served by public water supplies. Bibby and Cheyne in 1942 suggested the direct topical application of fluorides to the permanent

teeth of older children. Recent studies have been made by Knutson and Armstrong of the U. S. Public Health Service group, in which the teeth in one quadrant were treated and future development of caries noted and compared with an untreated quadrant as a control. These studies have indicated an approximate 40 per cent reduction in newly developed dental caries as a result of this procedure. The treatment is not effective in checking extension of caries on an individual tooth already attacked. Bibby² has recently been a strong advocate of the topical application of fluoride for prevention of caries.

If both the treatment of water supplies and the topical application of fluorine to the teeth were employed, there would be ample need for all the conventional facilities in the form of dental service which we can hope to provide. Gruebbel points out that in one Missouri county the adequate treatment of carious teeth in children between 6 and 14 years of age would require four-fifths of the time of all the dentists in the county. The studies of the Committee on the Costs of Medical Care showed that in 1929—at the peak of peacetime prosperity—the individual in the lower half of the population from an economic standpoint had on the average one-tenth of a visit to a dentist per year.

If the new knowledge in regard to dental caries can be practically applied it will make a contribution to the health of the people of the first magnitude. In all new developments of science there arise unsuspected obstacles, and we should always be on guard against any attempt to exploit them prematurely. The evidence seems, however, sufficiently clear to warrant carefully controlled experiments on "fluorinization" of water in communities where the fluorine content of water is low (which must obviously be continued over a period of years³); and the accumulation by dentists of more extensive evidence as to the effectiveness of topical treatment.

MEDICAL CARE FOR THE WIVES AND INFANTS OF SERVICEMEN

A YEAR of experience has now been accumulated with the Emergency Maternity and Infant Care program to provide medical, nursing, and hospital care for the wives and infants of enlisted men in the four lowest pay grades of the Army, Navy, Marine Corps, and Coast Guard, which became effective March 18, 1943.

The service is provided under plans administered in each state by the state department of health. It is available as a right to all families of servicemen in the specified grades with no humiliating means test; although it is naturally assumed that the ordinary community facilities, in the form of infant welfare stations and public health nursing service, will not be duplicated, and that infants of servicemen will be accepted by such agencies without financial investigation.

There were naturally misunderstandings and conflicts of interest in the inception of this program; and, in certain states, these conflicts aroused resentment which for a time weakened the confidence of the public in its public health leaders and in the medical profession. Fortunately, these difficulties have been overcome. The program is now in operation in all 48 states, Hawaii, Alaska,

Puerto Rico, and the District of Columbia. By the end of the first year of operation, it is estimated that maternity and infancy care will have been made available to a quarter of a million wives and infants of enlisted men.

The large number of cases cared for testifies to the generous coöperation of the medical profession in this essential contribution to national morale; and the fact that applications are being currently received at the rate of more than 30,000 per month evidences the satisfaction of patients with the service provided.

Our state health departments have met a serious challenge in providing the record-keeping and accounting involved in the application of so large a program. They have learned the job now and complaints from physicians and hospitals of delayed payment are less frequent than at first. The fact that 86 per cent of all maternity cases completed in December, 1943, were delivered in hospitals is highly encouraging; and letters from certain states indicate that applications for care are coming in earlier and earlier in the period of pregnancy.

Opposition to the program has centered almost wholly on the method of payment of physicians and on certain details with regard to the rate of per diem payment to hospitals (the latter difficulties being ironed out as the system evolves).

It has been proposed, for example, that instead of recompensing the physician or the hospital for the service rendered, the patient should receive a financial allotment of some sort and pay her own bills. Such a procedure would, however, be in contravention of the clear intent of the Congress which was to provide medical care and not a cash bonus, and it would obviously preclude the maintenance of any standards of quality of service. Medical economics has its well established principles as clinical medicine has; and one of these principles is that a cash indemnity plan inevitably fails. Artemas Ward once said, "There is a great deal of human nature in man." Enough patients will use their cash for other purposes than that for which it was intended—and enough doctors will add to their charge the amount of any available cash grant—to wreck any program founded on a cash indemnity basis.

A second suggestion is that the patient, if she desires, should be permitted to pay an additional fee to the physician or hospital beyond the rate of payment under state plan. If the doors were once opened to such a procedure, each wife of a serviceman would eventually be forced into a discussion with the hospital and physician as to the amount the traffic would bear and the basic purpose of providing for essential needs without a means test would be defeated.

A third criticism concerns the primary basis of payment to the physician. Consultant services and medical care for unusual conditions not directly related to maternity are provided on a fee-for-service basis, but the routine prenatal, obstetrical, and post-partum care is paid for on a flat rate per case. This system may work hardships on an individual physician who has a few exceptionally difficult cases, but will in general balance out and is eminently desirable from the standpoint of avoiding paper work for physicians and heavy administrative costs. Recent modifications of the plan provide additional fees for certain complicating conditions.

Finally, the actual size of the flat fee has been the subject of extended discussion. The care to be provided is not a "charity" service; nor is it, on the other hand, a luxury service. It cannot be expected that average fees will be paid on a level with the charges of city obstetricians. Discontent naturally arises from the fact that a physician who may, in his ordinary practice, be com-

pletely generous and unselfish in his service to the needy, naturally thinks of the fee he charges to the wealthy as the "normal" price for such service. If the government pays less than this "normal," he feels aggrieved. Yet such a physician actually obtains a far higher total income with fully-paid-up patients at \$50 a head than with a few large fees and much free service—at least, when dealing with such families as those here concerned whose heads are now receiving from \$50 to \$78 a month.

In spite of doubts and difficulties, the program has gone forward with notable success. In March, the Surgeons General of the Army and Navy addressed a special message of thanks to the physicians of the United States for their participation in this enterprise. "Physicians," they say, "the country over are contributing their medical skill in this wartime program generously and in return for moderate recompense. Hospitals the country over have opened their doors to these wives and their infants making available accommodations where their medical needs can be met adequately, though without luxury care. Nurses the country over are helping in the city and the rural homes and in the hospitals. . . . The morale in the armed forces is being raised and our fighting men go overseas with greater confidence in the security of their families because of this wartime program. We who are responsible for the health and medical care of the men in the armed forces are grateful to you—physicians, nurses, and hospitals—who are participating in this program of care for the wives and infants of these men. . . . Your contribution is an invaluable aid to us in the prosecution of the war."

The tribute is well deserved. Similar appreciation should also be extended to the state departments of health and certain city departments which have carried a heavy share in the burden of administering the program; and to Dr. Martha M. Eliot and her staff in the Children's Bureau who have wisely and courageously guided the course of one of the outstandingly valuable wartime efforts in the United States.

COMPULSORY TREATMENT FOR TUBERCULOSIS

Dr. William P. Shepard, Welfare Division of the Metropolitan Life Insurance Company, San Francisco, has called to the attention of the Managing Editor "an amazing and educational document which deserves wider dissemination." Dr. Shepard has secured the permission of the author, Honorable Marion G. Woodward, Judge of the Superior Court No. 3 of San Joaquin County, Calif., to publish the letter.

"My purpose in calling it to your attention," writes Dr. Shepard, "is that so many health officers, some of them lacking in experience, are so inclined to resort to compulsion when persuasion and education are the indicated procedure. Persuasion and education take so much more time and effort and are not always 100 per cent successful. Nevertheless, many health officers of my acquaintance at least do not appreciate the viewpoint expressed by Judge Woodward."

December 24th, 1940.

Dear Sir:

Your letter of the 17th, informing me of the death of Miss _____, a minor whom I refused to adjudge a ward of the Juvenile Court in order that she might be compelled to accept hospitalization, and taking me to task for failure to "coöperate," has been received.

It would serve no useful purpose to suggest the impropriety of your letter. The point of view behind it, however, interests me. Were it not for the fact that individual rights are being ruthlessly subordinated to the state the world over, I should be quite startled by the subtle implications of your language. But regardless of my personal reactions, the letter indicates that you have not considered the broader aspects of the problem.

First of all, I must point out that the Superior Court is not a benevolent or educa-

tional agency which may be expected to "coöperate" with community philanthropy or other worthy effort. Nor is it a Gestapo for dealing with those under-privileged members of society who have not caught up with our advanced standards and who often irritate us by their stupidity and lack of appreciation. On the other hand, the Court is a tribunal whose main function is to determine facts and declare the law applicable thereto. It is not at all concerned with the consequences of its official acts, nor has it any coöperative or other connection with the undeclared policy-making power of the State. This does not mean that judges themselves are always in personal accord with their judgments and decrees, or are unmindful of the fact that perhaps better social results could be obtained had a particular decision been different.

In the _____ case the young woman was not referred to "my court" for aid as that word is ordinarily understood. She had been living at home with her widowed mother and had violated no law. She was, therefore, neither a delinquent nor a dependent. Her home, it may be admitted, was humble and probably contained little more than the bare necessities of life; but she was happy and contented there and desired to remain, and her mother and brother wished her to do so. This being true, the petition for making her a ward of the Juvenile Court was somewhat of a subterfuge, although the broad language of the statute could have been made to fit the situation had I wished to avail myself of it.

The "aid" sought from me, in my official capacity, was a coercive order requiring the mother, against her will and without her consent, to place the girl in the _____ Sanatorium. In other words, the health authorities finding no necessity for quarantine measures, which, in many cases, may be resorted to when the public health is endangered, and discovering no law requiring the compulsory isolation of tuberculosis victims, thought it would be quite appropriate if the Juvenile Court would intervene and, under its wide discretionary powers, apply the necessary force. I declined to do so and have no apologies to make for the decision. Parenthetically, it may be observed that procedures of this kind are almost invariably

directed against illiterate and poverty-stricken individuals who must dumbly accept all official up-lift invasions of their private rights because they have neither the means nor, in many instances, the intelligence to resist.

The problem then has several aspects. You approach it from the humanitarian side, which is always a worthy approach and one that cannot lightly be brushed aside.

As an expert in a highly specialized field, you know that tuberculosis, one of mankind's greatest enemies, can best be treated in a well equipped and properly located sanitarium. Quite naturally you have little patience with a sufferer who fails to perceive so obvious a fact; and, from your letter, I gather that you likewise have little patience with a judge who apparently disregards scientific truth and, with a great show of obsequiousness to the rabble, sends a tuberculosis victim home instead of placing her in a hospital.

I do not wish to be too critical of this viewpoint, but I insist that there are other factors to be considered, especially if one is charged with any sort of governmental responsibility. I am well aware of those borderline cases where parental ignorance comes into conflict with recognized medical standards and where the hazard is more individual than public. And I am always sorely tempted to do *what I personally know will be best for the individual* even though there is some violation of personal rights. In some of these situations it seems fatuous to talk about personal rights. On the other hand, the most of us think and act, as the late Justice Cardozo once pointed out to the law students of Yale University, as our class thinks and acts; and, once we have arrived at an opinion with respect to what is good for others, we rather like the idea of giving it the force of the law. In the Juvenile Court this thought is constantly uppermost in my mind. The hearings are held behind closed doors and the persons involved are not only helpless but seldom represented by counsel. How easily then the Juvenile Court could degenerate into a star chamber proceeding with the judge imposing his own particular brand of culture and morals on indigent people—all under the guise of an extraordinary emergency!

Under our form of government, the family is the unit of society and the relation of parent and child should not be judicially disturbed unless the family situation is intolerable according to minimum standards. Ordinary poverty is generally the excuse but it is not always a justification for interference. And the same may be said for illiteracy. In

other words, a poverty-stricken illiterate does not necessarily by that fact alone, forfeit the natural right of being the head of his family and making decisions for his minor children. These decisions are not always wise, and I have already said, there are many occasions when I am sorely tempted to override them and make the decision myself. The law is broad and these invasions of personal liberty can always find justification in the fact that a benefit is to be conferred on the recipient.

It should never be a question of what a judge has the *power to do* under broad statutes and conflicting legal precedents, but what he *ought to do*, keeping in mind always the entire picture of personal rights and their historic background. In recent years we have seen whole populations abroad yield to the seduction of paternalism, with its promises of prosperity and a better life, only to be ruthlessly exploited and persecuted. We do not want the lust for power which is now dominating the minds of so many little men, to wreck our heritage of freedom and individual initiative. To this end judges cannot approach any problem, even that of providing medical care for the indigent, without being alert to fundamental rights. Because a thing is good for an indigent does not always justify the application of force. If we could speak with absolute finality as to what is good and what is bad perhaps the end would often justify the means. But we cannot do this.

When a child needs medical or surgical care and is without parent or guardian, as often happens, I am only too glad to furnish the necessary consent. But when a parent, because of ignorance, opposes a particular method of treatment for his child, I do not always feel that I am justified in using compulsion, although I find myself out of sympathy with his viewpoint. Such was the case with the _____ family. One child had previously died after hospitalization and the illiterate mother believed that _____ would also die if sent away from her home. You may rest assured that I did not overlook the possibilities of this situation. Because our Juvenile Court sessions are quite informal, I spent the greater part of an afternoon trying to persuade the mother and the girl to accept the medical advice which had been given them. I pointed out the advantages which your splendid sanitarium offered and also the probability of death if the girl remained at home, but I could not penetrate the stupidity and superstition of these people and the session ended with considerable unpleasantness. I did, however,

respect their rights and I would do the same again.

Of course, as you must know, I am under no obligation to justify or defend any decision I may be called upon to make. I thought, however, you would appreciate this viewpoint which I have developed at too great a length.

Wishing you continued success in your work, I am,

Very truly yours,

AN OUTSTANDING EXAMPLE OF JOINT PLANNING

It is common to hear commendation of the benefits of joint planning by several agencies, but it is rare to find an example representing so complete a coverage as the following.

Nassau County, N. Y., a populous suburban area near New York City, located on Long Island, has a full-time county health department of which Earle G. Brown, M.D., is Commissioner. There is a County Tuberculosis Sanatorium of which James Walsh, M.D., is Superintendent. There is a County Tuberculosis and Public Health Association, of which Mrs. George E. Brower is President and of which Miss Frances H. Barbour is Executive Secretary.

The Tuberculosis and Public Health Association faced the year 1944 like many other similar voluntary groups with an unbudgeted surplus from the Christmas Seal Sale available for its program. At their initiative and with the coöperation of the State Committee on Tuberculosis and Public Health, George J. Nelbach, Executive Secretary, the State Commissioner of Health, Edward S. Godfrey, Jr., called an informal meeting to consider constructive suggestions for the expenditure by the Tuberculosis and Public Health Association of an unbudgeted balance of approximately \$22,000. Represented at the conference was the State Department of Health through the Commissioner, with the General Superintendent

of State Tuberculosis Hospitals, the Director of the Division of Syphilis Control and the District State Health Officer from his staff. Two members of the Nassau County Board of Health and the Commissioner of Health were in attendance, and the Medical Superintendent of the County Sanatorium. The President and the Executive Secretary of the Tuberculosis and Public Health Association, the Executive Secretary of the State Committee on Tuberculosis and Public Health and his assistant, and the Field Adviser to the Nassau County Association were present.

The conference explored fruitful expenditures for mental hygiene, for the expansion of tuberculosis case finding and services among family contacts, for the transportation of tuberculosis patients and family contacts to clinics, for the x-raying of general hospital admissions, and other parts of the tuberculosis program, such as rehabilitation. Other subjects were given consideration, such as the need for an expansion of adult health education services in tuberculosis and venereal disease control.

The entire meeting was reported in minutes which, as a pattern, may prove interesting to other agencies wanting to make group planning a reality. Copies may be obtained from Robert W. Osborn, Assistant Executive Secretary, 105 E. 22nd St., New York, N. Y.

CENTRALIZATION AND DECENTRALIZATION

In an article entitled "Shaping the Future of City Planning" (*Better Times*, December 31, 1943, published by the Welfare Council of New York City), Dr. Neva R. Deardorff, Assistant Director of the Welfare Council, discusses the individualistic restricting of the city's services—fire and police protection, health, welfare, public schools. In New York none of these services use the same districts, or boundaries; only the Health Depart-

ment follows census tract boundaries. The result is that pertinent social data cannot be organized for the various school districts, welfare, or police districts. The effect of highly centralized city services, therefore, is a total decentralization for any community served and an utter confusion for the ordinary citizen as to where his government functions. Her article is illustrated with a map of one area showing the crisscrossing lines of the five city departments in comparison with which she says "a crazy quilt would appear orderly in design."

Dr. Deardorff's remedy is a fairly simple one: the districting of the city into a number of population groups with a civic center from which would radiate the city's services, each of which might have a different number of subdistricts but none would overlap the larger boundaries and none would violate census tracts. The actual building that housed the central offices of these services in each area would inevitably develop into a civic center and a symbol of government as it affects the day-to-day life of the citizen.

It occurs to us that this thinking has much in common with the planning of the Association's Subcommittee on Local Health Units. On the one hand, New York needs to rescue itself from the chaos of vertical centralization without horizontal coördination. On the other hand, the less populous areas of the country need for public health purposes, and undoubtedly for a great many other public services, a centralization of the numerous and overlapping responsibilities of small and uncoördinated units of government into a centralized unit large enough both to justify and support an adequate public health organization.

The horizontal coördination of various public services, the need for which is illustrated in the New York City situation, is not being lost sight of in the planning of the committee in that,

with a few notable exceptions dictated by peculiar local conditions, county boundaries are not being violated in setting up local health units, although several counties may be joined together to form one health unit. Further, close collaboration with the U. S. Public Health Service Division of Hospital Planning assures that the planning of health and hospital jurisdictions does not overlook the need for horizontal coördination.

A NEWS LETTER YOU'LL READ TO THE END

The Venereal Disease Control Division of the Oklahoma State Health Department, Dr. G. F. Mathews, Commissioner, is responsible for an unpretentious, 2 page, mimeographed *News Letter* so beguilingly written that you are irresistibly lured to the end once you start it. Don't be misled by the adverbs. There is nothing whimsical or sentimental about it. It is full of wallop, unwelcome truth, and debunking of smug attitudes. We quote almost the entire first page of the February issue.

That loud noise you just heard amounts to practically nothing. It was only the soldier-sailor contact reports ringing the bell for a new high in Oklahoma. Central Registry figures show that 372 service men were reported in January to have been infected with a venereal disease in this state. This compares with a former high of 358 in August and represents an increase of 30.9 per cent over the month of December when 284 infections were reported. Maybe it's just one of those things, a bad month when all the little spirochetes and gonococci got together and decided to put on a real show. And then again maybe this is the real thing. Maybe the textbook theory that venereal disease rates must inevitably increase in wartime is about to overtake the inch-by-inch progress for which we have so stubbornly fought during the past two years.

Whatever the reason for this unexpected and totally unwelcome increase in service men infections, let's not be fooled by the comparatively good showing we have made in the Eighth Service Command for the same period. We have used that report too long as a criterion for what we have done and

what we must do. From now on, figures released through this publication will be Central Registry over-all tabulations. The Eighth Service Command figures make up only a part of the picture. For example, in January Oklahoma City had 39 contacts reported from the Eighth Service Command, but when all soldiers and sailors who were infected in Oklahoma City were totalled, it amounted to 89 infections. Tulsa had 18 infections reported in the Eighth Service Command report, but from all service commands, both Army and Navy, 48 infections originated there. And so on. . . .

We heard during the past month of an early syphilis patient who finally named 17 contacts but who gave only one on the original interview because the interviewer was satisfied with just one; of a contact who was able to get the name and even the clinic and patient number of the informant (that's nearly as confidential as a newspaper headline); of a wife who got a letter saying that her husband had gonorrhea and she would have to come into the clinic for an examination; of an acute gonorrhea contact who was not brought into the clinic for an examination because she was on her honeymoon in an apartment three blocks away.

RESPONSIBLE TO WHOM?

Health officials who may sometimes ponder the question of their responsibility will be given food for thought by the following occurrence. In a midwest state an outbreak of typhoid fever assumed sizable proportions with 6 deaths being reported. State health department officials promptly began an investigation and convicted "a product" (unnamed) which thereupon was "taken off the market," it was announced.

Understanding citizens in the affected region may have wondered what the "product" was and later whether they had any of it in their own cupboards—when a paper "leaked" the information that the product was cheese. One newspaper editorialized upon the action of the state health department in withholding the information in this vein:

Granting that the firm was not at fault and may suffer some financial loss as a result of the publicity given it, the fact still remains

that the public is entitled to know just how and where the epidemic started. In the first place some of the company's suspected products might still be on hand in some kitchens, and in the second place all manufacturers of cheese and butter would naturally come under unjust suspicion if the name of the offender had been kept secret. A policy of laying all the cards on the table is usually best anyway in all such matters of public interest or welfare.

We are indebted to the *Health Officers News Digest*, published by the Public Health Committee of the Cup and Container Institute, for the above, which as a proffered contribution to the former, seemed to its editors and to us, a thought-provoking question to pass on to readers of *Credit Lines*. It reached *Credit Lines* while a recent report from a Food and Drug Division of a State Health Department was under review. The reviewer was particularly receptive because he was already infuriated by the careful anonymity shrouding "products" which had admittedly been found on examination to be unfit for human consumption, or dangerous to the public health. We echo the question, responsible to whom? Responsible to the manufacturers of "Product A," or the wholesale outlet for "Sample 102," so that the worthless stuff may continue to be profitable, or responsible to the people whose health they are employed to protect?

DADE COUNTY TURNS OUT ITS FOOD HANDLERS

One of the most successful schools for food handlers yet conducted by U. S. Public Health Service's Major L. H. Male and Dr. T. H. Butterworth was sponsored March 14–21 by the Dade County Health Department, Miami, Fla.

The course, covering primary phases of sanitation, bacteria, personal hygiene, food poisoning, storage, and refrigeration consisted of three lessons, each repeated four times. The subjects were

dramatized and supplemented by demonstration, slides, and moving pictures.

Total attendance was 4,738 and included home economic classes, the KP contingent from the local Naval base, and personnel from virtually every type of eating establishment in the county. There was seldom "standing room" in the Central School auditorium where the course was held, and Major Male declared he "hadn't seen anything like it," when asked to compare the attendance with similar schools he has conducted.

Russell Broughman, Bureau of Sanitation director for the County Health Unit, had more than 3,000 food handlers registered through his sanitary inspectors before the school opened—the remaining were registered at the school.

Careful check was kept of attendance, and each person who attended the required three classes received a certificate. Establishments that enrolled 75 per cent of their personnel also received certificates. Some eating houses compelled their entire employee group to attend the course and some even closed at specific hours to allow the personnel to take advantage of the free classes of instruction.

At the suggestion of the Florida State Board of Health, sanitation officers from other county health units attended the course, with the aim of holding similar schools periodically in their counties. Coöperating with the Dade County Health Department and U. S. Public Health Service was Robert G. Carter, technical sanitarian of the Florida State Board of Health.

DR. ROBERT HUGHES PARRY AT HOME

More than 3,000 public health workers in western states and several hundred persons in New York City and elsewhere in the East had the opportunity to meet Dr. Robert Hughes Parry, Health Officer of Bristol, Eng-

land, when he visited the United States last spring. They will be interested in an account of a recent week-end which Dr. Albert S. McCown, formerly Medical Director of the American Red Cross, and now an officer of the U. S. Army stationed in England, spent with him at his home in Bristol.

Excerpts from Dr. McCown's letter follow:

I went down to Bristol on the Saturday morning train, arriving in time for lunch, stayed over Sunday, made some official visits Monday morning, and returned Monday afternoon.

I cannot tell you what a satisfaction it was to see Dr. Parry in his home environment. His wife is a charming person, a Captain in the British Medical Corps, doing a splendid job in the transfusion service. I shall not attempt to describe their home; their gardens; their friends; nor the place they occupy in the life of Bristol. You will have to come and see it for yourself, and I do hope that some day you will have that privilege.

The purpose of this letter is to confirm for you and the other members of the troupe the accuracy of Dr. Parry's descriptions of Bristol, as immortalized in the famous opus we heard on so many occasions.

First of all, of course, I saw the famous River Avon, down which some famous journeys were made. John Cabot, among others, sailing out to discover a new world, not forgetting that one of the promoters of that voyage was the Sheriff of Bristol, a Mr. Americke. Dr. Parry insists that "whatever the Italians say, we in Bristol *know* that that was the origin of the word America."

Bristol is a City of Churches, mostly burnt out now, built with money made out of the slave trade, a sort of Beveridge scheme for the next world. Now, in the year of our Lord 1944, we find that Bristol's gift of slaves is being returned to Bristol with interest.

I saw, too, St. Mary of Redcliff, which Queen Elizabeth said was the most beautiful Parish Church in England, and so it must be, because no one has ever dared to disagree with Queen Elizabeth!

Sunday afternoon we drove up the road to Cheddar, through the rocky Combe of Barrington, where the Vicar of Blagdon, the Rev. A. M. Toplady, caught in a storm of thunder, lightning, and torrential rain, found refuge in a cleft in the rocks, and, as a result of that experience, wrote the hymn, "Rock of Ages, Cleft for me, Let me hide myself in thee."

On the way back we passed the quay-side of the Port of Bristol, immortalized by Robinson Crusoe and John Silver, and on past the site where St. Peter's hospital used to be, and where worked William Budd, the father of epidemiology. I saw no statue to Jenner. Undoubtedly this would not have been permitted by the anti-vaccinationists, since Bristol is their headquarters. I saw the little brick "cottages"—with their amenities. (Just between you and me they are really two story brick houses but the Bristolians insist on calling them cottages, and cottages they must remain.)

From without, I worshipped at the Chapel of John Wesley, the Founder of Wesleyism and saw the Castle stormed by Sir Thomas Fairfax during the Cromwellian period. It was the same Fairfax family who figured so largely in early American history, it being a Lord Fairfax who owned tremendous estates in Virginia who was surveyed by a youthful George Washington.

In Dr. Parry's own home I saw a Morrison style shelter, just as he had described it. Fortunately there was no necessity to use it during my visit.

So completely delightful was the trip, and so wholehearted the welcome, that Hugh Smith and I plan to go down for another week-end in the near future.

RHEUMATIC FEVER

"Fortunately," says the Children's Bureau, "there is increasing interest in many states and communities in the problems related to the rheumatic child." New releases by the Bureau on the subject include a 4 page pamphlet entitled "Some Facts about Rheumatic Fever" packed full of information. It is to be regretted that a subject of such great importance has to be presented in a format and make-up that reflect some of the limitations under which federal agencies operate in the printing field.

Also being currently distributed by the Bureau is a table showing the state services for children with rheumatic fever that were financed in whole or in part by official state agencies under the Social Security Act, Title V, Part 2, for the year ending December 31, 1942.

The Wisconsin Anti-Tuberculosis Association Social Workers' *Bulletin*

dated March 20, 1944, begins what is apparently a series of articles on the subject of rheumatic fever and heart disease. It calls attention to the fact that more than 7,000 children in Wisconsin have rheumatic heart disease, that rheumatic fever produces nearly 50 times as many cripples and semi-invalids as infantile paralysis, and that the disease is responsible for more deaths of children under 15 than tuberculosis. It then goes on to discuss cause, onset, course, complications, and treatment. Its purpose is evidently to inform a non-technical audience, and is well served. Miss Metta Bean, Director of Social Service, signs it. We shall watch for the next issue.

"WHAT YOU NEED TO KEEP STRONG AND WELL"

The Maternal and Child Health Division of the Georgia Department of Health has prepared an informative chart which teaches elementary nutrition lessons in brief text and pictures. Three concentric circles around a sketch of two children show in the first circle "what you need"—vitamin D, vitamin C, etc. The second and third circles synchronize "what it does" and "where you find it," respectively, with vitamin D, vitamin C, etc. The chart is reproduced in black and white with a red border, probably the colors of the original, in *Georgia's Health* for February, published by the Georgia Department of Public Health, Thomas F. Abercrombie, M.D., Director.

CHILDREN: \$7,763 EACH

Health workers who are seeking data to emphasize the money value of human life will be interested in the computations recently published by the Metropolitan Life Insurance Company through the *Statistical Bulletin*, Volume 25, No. 1, January, 1944. Tables are presented showing average expenditures

for bringing up a child to the age of 18 by type of expenditure and by various family income levels. Similar figures are presented year by year showing how the accumulations are arrived at.

According to these figures, it costs \$7,763 to bring up the average child in a family with \$2,500 income and, for a family with \$5,000 to \$10,000 annual income, the average figure rises to \$16,337.

MORE ON ANNUAL REPORTS

It is difficult to do justice to an annual report of a health department, a voluntary agency, a hospital, or any other organization in anything but a full-length review. Too much time and effort go into their preparation to brush them off lightly, even if, as the lad with the harmonica said, "I blow it in so sweet and it comes out so sour."

Because full-length reviews are out of the question, we had decided not to talk about any. In spite of this commendable determination, a handful of especially striking ones, from a variety of sources, for one reason or another, persistently haunts us, and to lay their ghosts, we give them brief mention. They were all blown in sweet and came out that way.

Dr. Edward G. McGavran, Commissioner of Health, St. Louis County Health Department, Clayton, Mo., issues his annual report for 1941 and 1942 under the title "St. Louis County Health in Defense and War." The front cover reproduces a photograph of the attractive new building. There is good balance between readable text and sketches, maps, and graphs. The budget included is unencumbered and understandable.

The Fifth Annual Report of the Housing Authority of the City of New Haven, Conn., which is called "Then and Now" and is Chapter Three of a series, is an appealing document, with

excellent photographs facing nearly every page of text and a double spread in the center. Seeing it reminds us that it is important not only to build good houses but to interpret the project to the public. This is good interpretation.

Dr. Charles F. Wilinsky, Executive Director of Beth Israel Hospital, Boston, Mass., makes his report for 1943 a living document even for those who have no particular reason for being concerned with its contents. There is a nice balance between the more systematic narrative and the tables, photographs, and other information.

Interesting approaches to a method of bringing to a community an understanding of its health problems have been used by the State of Nebraska's Department of Health, C. A. Selby, M.D., Director, and by the Spartanburg, S. C., County Health Department, John B. Gelzler, M.D., Director. The first is an almanac, true in size, mustard-yellow cover, news-print paper, and arrangement—true in everything but content—to the old-fashioned kind that used to be put out by Glover's Mange Cure or something similar. The second is a calendar with photographs and a minimum of text.

In "Fifty-Two Weeks with the Louisville and Jefferson County Health Department," Dr. Hugh R. Leavell, Director, takes you through the year and through his department, provocatively and illuminatingly. He rings the bell with his various devices all the way from the title page on through the simple but revealing diagrams of the first page, through the excellent letter of transmittal and into the body of the report.

Small in size, only $5\frac{1}{4} \times 3\frac{1}{2}$ inches as it goes through the mails, but telling a big story in its 8 pages, the 26th annual report of the Maternity Center Association, 654 Madison Avenue, New

York, N. Y., is arresting with its title "A Letter from the South Pacific." The introductory copy is moving and the five paragraphs of "some of the things the Association has been doing" are masterpieces of condensation.

"Health Progress through Team Work and Citizen Participation" is the 26th Annual Report of the Public Health Federation and its Councils, Cincinnati, Ohio, Bleecker Marquette, Executive Secretary. Well printed and illustrated, it is a remarkable record of exactly what its title describes.

In tabloid newspaper form, the Warren County Health Department, Bowling Green, Ky., Paul Q. Peterson, M.D., Director, distributes its annual report. It does not have to depend on health department envelopes for mailing. It goes as a special section of the *Park City Daily News*.

"Health in Hartford" for the years 1941 and 1942 is an ambitious 90 page book to which each Bureau has contributed a chapter. It is a factual, detailed account of the activities of a wide-awake, effective health department. Three merged photographs on the cover cleverly assemble laboratory beakers, motion picture reel, the National Health Honor Roll plaque, and other objects relating to each aspect of the department's work. The Health Officer of Hartford, Conn., is Alfred L. Burgdorf, M.D.

Photographs, sketches, maps, and graphs enliven the 54 pages of the "Report on Health and Safety Project of the Girl Scouts, 1939-1942." A comprehensive job has been done here both in the project and in the report. The story is worth telling and is well told.

WORTH QUOTING

Sir William Beveridge suggests as peacetime objectives "making men as free as is humanly possible of the five giant evils—of want, of disease, of ignorance, of squalor, and of idleness, the idleness enforced by mass unemployment. I believe that if we attack those first four giants with all our might, if we spend ourselves generously and our money wisely against want, disease, ignorance, and squalor, we shall find that in the process we have killed also the fifth giant of mass unemployment."

Henry Wallace says—"Second to good and plentiful food I would put good and plentiful hospitals. With more hospitals adequately equipped and staffed, combined with a common sense public health program, we can stamp out tuberculosis, syphilis, and possibly malaria. . . . We ought to be spending 4 times as much on hospitals and doctors and nurses as we are now spending. . . ."—Reprinted from *Washington News Letter on Social Legislation*, February 23, 1944.

BOOKS AND REPORTS

Soviet Health Care in Peace and War—By *Rose Maurer*. New York: *American Russian Institute for Cultural Relations with the Soviet Union, Inc.* (56 West 45th Street), 1943. 48 pp. Price, \$.10.

Soviet Health Care in Peace and War is a pamphlet 48 pages in length, giving a descriptive but uncritical review of what the Soviet Union has planned and has been doing in the care of the health of its citizens before the Nazi attack and since. The brochure begins, quite appropriately enough, with the discussion of health protection at the place of work, and then treats briefly such subjects as District Health Centers, Special Care for Women, Child Care, Rural Medical Service, Medical Education, etc.

The reading of this brochure affords one a rather general idea of what the Soviet Union has been trying to do in the way of health conservation. One cannot, however, obtain a clear idea as to how the plans have worked out from the data given. The statistics quoted by the writer are rather crudely formulated and frequently are quite unintelligible.

In the Section "Health Statistics" (page 25), there are some rather meaningless comparisons made between the prevalence of certain diseases in Russia and in the United States. They are meaningless because it is doubtful whether the reporting of morbidities in Russia can possibly approximate that of the United States. There is a marked absence of mortality statistics by which medical service and the state of the health of the people might somehow be gauged.

In these respects then the brochure is seriously deficient.

Part II, which is devoted to Soviet Medical Care in Wartime, makes particularly interesting reading since it describes how the Soviet Union has met the problems of the health care of its vast army.

The pamphlet is tinged with a propagandistic color, which is understandable enough, but one is left with the wish that it had more solid facts and fewer vague generalizations.

IAGO GALDSTON

The Hospital in Modern Society—By *A. C. Bachmeyer, M.D., and Gerhard Hartman, Ph.D.* New York: *Commonwealth Fund*, 1943. 760 pp. Price, \$5.00.

It is interesting to note how exceedingly few textbooks have been written and are available on the subject of hospital administration. This is true in spite of the fact that hospitals represent an investment of over 4 billions of dollars, employ normally a million people, and there is expended annually in excess of 800 millions of dollars for the hospital care of the American people. Surely the enormity of this structure and the tremendous volume of service rendered justifies the ready availability of authoritative material on the essential aspects of hospital service.

The great need for information for the guidance of hospital administrators, their personnel, and others interested in this field, has been met by some of the many articles which appear in the three leading monthly hospital journals, as well as in those dealing with medicine, public health, nursing, etc. The knowledge, experience, and broad background developed over a period of years by the able authors of this book have been applied to the careful compilation of

papers published for more than a decade on the subjects of great interest to those concerned with the varied services involved in hospital management. It is not too much to claim that the list of authors of these articles includes the leaders in the field of hospital administration, as well as in intimately related fields.

The strength of this book lies not only in its inclusion of carefully selected reading material on varied subjects, but also in the provision at the conclusion of each chapter of a substantial list of "References for Further Reading." Totalling 760 pages, divided into 5 parts, and 19 chapters, and including approximately 150 articles and committee reports, it should be a welcome addition to the too meager number of textbooks on this important subject. It should serve as a ready aid and guide to hospital administrators, and their assistants, hospital department heads, trustees, and others concerned with hospital administration.

CHARLES F. WILINSKY

Statistical Abstract of the United States, 1942—U. S. Department of Commerce, Bureau of the Census (64th ed.). Government Printing Office, Washington, 1943. 1,097 pp. Price, \$1.75.

The 1942 *Statistical Abstract* is the 64th edition of this compendium of the industrial, social, and economic history of the United States as portrayed in figures. In 996 tables, 35 basic subjects such as Vital Statistics, Social Security, Manufactures, Banking and Finance are summarized, an increase of 144 tables over the 1941 edition covering the same subjects. In contrast, the 1920 edition covers 15 basic subjects in 462 tables.

Like the dictionary, this volume has no plot and, like that volume also, one can spend many interesting and enlightening hours with it, for it con-

tains both solidly practical and esoteric information. One finds, for example, that Vital Statistics first appeared as a major subject in 1921 with 12 tables; by 1942 professional and public interest apparently required 22 tables to cover the subject adequately. Social Security first appeared as a major subject in 1939, with 13 tables; in the 1942 edition it has 39 tables.

This reviewer was interested in finding out what was happening in the field of manufacturing in those years when our world was whirling all too ignorantly to its present catastrophe. Between 1937 and 1939—the latest figures available—tobacco, rayons, apparel, both men's and women's, millinery, fur coats, silverware increased in number of workers and value of products, but iron and steel, electrical, agricultural and other machinery, automobiles, railroad equipment, petroleum products, even food products, decreased. Only aircraft and shipbuilding, among the basic manufactures later to be supremely important for war production, were greater in 1939 than in 1937.

As in other recent years, the present volume has a Bibliography of Sources of Statistical Data and each table is annotated as to its source.

MARTHA LUGINBUHL

Trends in Nursing History—By Elizabeth Marion Jamieson and Mary Sewall (2nd ed). Philadelphia: Saunders, 1944. 651 pp. Price \$3.00.

The second edition of *Trends in Nursing History* brings the events in the nursing world up to date—as of October, 1943. For a rapid review and an encyclopedic type of reference book, this *History* serves. It lacks continuity of subject development and omits reference to some of the important and colorful original sources which make history come alive for the student.

Events, people, and organizations in their proper chronological order are

described without much critical evaluation. The result is a "spotty" narrative, which nevertheless covers an amazing range of topics. Chapters XI-XV offer fairly satisfactory background reading for students ready to tackle current events in class discussion.

DOROTHY DEMING

Clinical Laboratory Methods and Diagnosis—By R. B. H. Gradwohl. (3rd ed.). St. Louis: Mosby, 1943. 2 vol. 2,130 pp. 57 color pl. Price, \$20.00.

Because of the accumulation of material dealing with laboratory examinations, this work now occupies 2 large volumes containing a total of 2,130 pages, exclusive of 100 pages of index (duplicated in each volume) and accessory pages. It is a veritable encyclopedia of information of value to any person having an interest in diagnostic bacteriology, parasitology, serology or chemistry and related fields. However, it is a work on methodology and is not a textbook for students or a manual for amateurs. It assumes a good knowledge of each subject covered. It includes chapters on hematology, blood grouping and transfusion, blood and urine chemistry, and covers an impressive range of special tests and technics in all of these fields, as well as in vitamin deficiency diseases, atopy, food chemistry, pregnancy, semen appraisal, toxicology, and the like. There is an interesting chapter on detection of crime by laboratory methods, and others on autopsy technic, preparation of museum specimens, and tissue cutting and staining. There is a discussion of penicillin. The chapter on the serology of syphilis is especially extensive and detailed. Practically any laboratory procedure (or an alternative) that is likely to be of value in medicine, toxicology, and related fields is to be found here with pertinent commentary, interpretations, and references to literature

both old and recent. There are 57 color plates and scores of instructive half-tones and line drawings. The chapter on supplies and equipment should prove helpful to those setting up new laboratories as well as to others responsible for laboratory work.

It seems probable that no author can prepare such a monumental work free from error or from statements with which some readers will disagree or from basis for criticism as to choice of material. Bacteriologists will find some reason for complaint in these respects, and so doubtless will specialists in other fields. However, the volumes under discussion share these common failings, in no excessive degree, so that the 3rd edition of this book may be recommended as a highly valuable contribution to any technical book shelf. The printers, proofreaders and binders and publishers are to be congratulated on a fine job of book manufacture. MARTIN FROBISHER, JR.

Occupational Lead Exposure and Lead Poisoning—*A Report Prepared by the Committee on Lead Poisoning of the Industrial Hygiene Section of the American Public Health Association.* New York: American Public Health Association, 1943. 67 pp. Price, \$.75.

This publication brings together in a small volume the important facts known about lead exposure and lead poisoning. According to the foreword, "The purposes of this report are (1) to outline practical and effective measures for the recognition and prevention of hazardous lead exposure in industry, (2) to describe satisfactory methods for the differential diagnosis and treatment of lead intoxication, (3) to point out the factual requirements for medico-legal purposes and the means of satisfying such requirements, and (4) to refer the reader to selected sources of more detailed and comprehensive information." These four purposes are

admirably carried out, and the professional ability of the eight men on the committee is excellent evidence that the information is reliable. The appendix gives a very informative classified bibliography for those who wish more details on any phase of the subject. This volume should have a wide circulation among physicians, industrial engineers, and clinical pathologists.

FRED J. WAMPLER

Educators Index of Free Materials
—*Edited by John Guy Fowlkes. (29th ed.). Randolph, Wis.: Educators Progress League, 1944. 165 pp.*

The *Educators Index of Free Materials* gives clear proof that schools do more than give lip service to the oft-heard doctrine of "enriching the curriculum." The *Index*, of which Dr. John Guy Fowlkes, Professor of Education, University of Wisconsin, is editor, made its first appearance in March, 1937, and is now serving approximately 100,000 teachers in all sections of the country.

Printed on stiff, 3-ply index cards, 5 x 7½", it is revised annually and semi-annually; the present edition of January, 1944, is its 28th revision.

The *Index* covers the whole school curriculum, and the sources of the free material listed include departments of the federal government, foreign governments, agricultural experiment stations and other state institutions, chambers of commerce, travel bureaus, human welfare foundations, and industrial concerns.

Health education is given due place in the *Index*. Also, under Wartime Education are found materials on first aid, guidance, nutrition and diet, physical fitness and recreation; under Applied Arts, home economics, including family relationships and child craft, foods and health, housing. Under Science and under Social Studies are found a variety of materials bearing on

the health field. Health films, slides, charts and posters are listed under Visual Education. Altogether, upward of 2,000 annotated materials, free for the asking, are listed in this *Educators Index*.

Many of the names of the professional health agencies do not appear in the *Index*. The listings under Health Education do not form a well rounded presentation of this subject; obviously, the reason is that free materials on all phases of it are not available. Are we, as professional health educators, doing all that we might to make sure that the schools are well provided with the best there is in this field?

The *Educators Index* is more than a useful tool to schools. It is a valuable stimulus to starting a school library. Moreover, it offers a challenge to the health profession to see to it that good free material is made available to the schools covering the whole field of health education.

LOUISE STRACHAN

Vital Statistics Rates in the United States: 1900-1940—*By Forrest E. Linder and Robert D. Grove; supervision of Halbert L. Dunn, M.D. Bureau of the Census. Washington: Supt. of Documents, 1943. 1051 pp. Price, \$1.75.*

This is one of the most useful books that have ever appeared in the field of vital statistics. It is difficult to review because each of the 71 tables presents fascinating statistical vistas that invite exploration. The volume is the more welcome because its predecessor, *Mortality Rates, 1910-1920*, is now over twenty years old.

As to the general structure of the volume, it is to be noted that of the 71 tables, 45 give mortality rates, 9 give natality rates, and the remaining 17 give underlying population tables. Numbers of births and deaths are not given. To have done so would have doubtless

made the volume too bulky. Nevertheless, these numbers can, if necessary, be calculated from the population and rate tables.

Roughly, a fourth of the tables give data for each state. A few show city and county data. Summaries for the expanding registration area are given for nearly all of the tables. Only four of the mortality tables, however, show time series for the registration states of 1900. This, in the opinion of the interviewer, is somewhat regrettable, for expansion of the registration area from the ten original death registration states (plus D. C.) in 1900 to the whole United States in 1933 brought into the area increasing proportions of young, colored, southern, and rural populations. These distortions can to some degree be neutralized by using tables which are specific for age, race, etc. What is more disturbing statistically is that, in expanding, the registration area took in states with less complete birth and death registration and probably poorer diagnostic standards. The book might, therefore, have profited by including more summaries for the registration states of 1900 or 1910.

About half of the tables have a cause of death breakdown. By skillful use of abridged lists it was found possible to pack into this volume a considerable amount of cross tabulation of cause of death with age, race, sex, and month. The occupational breakdown was omitted, probably wisely, because of its limited usefulness in relation to the amount of space demanded. Marital status has also been dropped.

It is, of course, practically impossible to set up an ideal set of tabular patterns until the tables have actually been in use. It may be helpful, therefore, to indicate the information which the reviewer has already sought in the book without success.

1. A tuberculosis time series by sex for single years near 1918.

2. Certain time series for the original registration states by age-cause-race.

3. Data for broad age groups such as 45 or 55 and over. To calculate these from rates and populations would be a considerable chore.

4. Data for age one. The decline in mortality probably was heaviest in that year. The tables give ages 1-4 only as a group.

In general, it appears that cause of death data could profitably have been expanded; and some of the space-consuming state tabulations left to state offices for publication. On the whole, however, reference to the book has been notable for the large proportion of successes rather than by the few failures.

The introductory text covers 119 pages. Although much of this information is extremely interesting, this reviewer questions whether so much general didactic information was necessary or desirable for a book of statistical tables. Philosophical discussions may interfere with proper reference to statistical tables by concealing basic definitions, indexes and explanations. Most of this material really belongs in a textbook.

Chapter 4, giving an informing, though somewhat extended discussion of age adjustment of rates is relevant, in view of the omission of standardized death rates from the volume. Chapter 5, entitled "Description and Explanation of the Tables," is quite essential to the proper use of the volume and the reader is urged to go over this chapter carefully. The ingenious tabular indexes in this chapter should be studied with particular care. These eleven pages should be used more than any others in the book and a permanent book mark or thumb index of some sort is advisable. Some readers may wish to include a column for residence allocation, which unfortunately was not included in the table.

One of the most commendable innovations is that the volume has been reduced to a cover size which, unlike

the earlier mortality volumes, will fit a standard bookcase, is easy to handle, and can be kept or used on a desk without upsetting ink wells or monopolizing undue space. This is fortunate, for every person with any interest in vital statistics will want to keep this excellent little volume constantly within arm's reach. Unless this reviewer is mistaken, the book will exert a profound effect upon public health thought and action for years to come.

A. W. HEDRICH

Rockefeller Foundation—International Health Division, Annual Report, 1942—*New York (49 West 49th Street)*. A limited number of copies available upon request. 194 pp.

This report presents the activities and expenditures of the International Health Division for 1942 under the following headings: Control and Investigation of Specific Diseases, Aid to State and Local Health Services, Public Health Education, and Table of Expenditures. The diseases under investigation and control included yellow fever, influenza, primary atypical pneumonia, typhus fever, rabies, malaria, diphtheria, scarlet fever, tuberculosis, hookworm disease, and syphilis. Studies of nutrition and mental hygiene were also reported.

The work on yellow fever included further studies and extensive use of yellow fever vaccine, with particular attention to post-vaccination jaundice associated with the employment of human serum in the vaccine. Also, the epidemiology of jungle yellow fever in Colombia and northeastern Africa received special attention. The work on influenza was concerned mainly with the immunology of the disease and attempts to develop an effective vaccine. In typhus fever, the relationship between classical and murine strains was studied, and new insecticides against lice were developed. Rabies vaccine prepared by treatment with chloroform

was shown to maintain its effectiveness for a least a year for the immunization of dogs. Malaria studies included a search for better chemotherapeutic agents and studies of immunology and histopathology of malaria, and the morphology of *Plasmodium falciparum*. Extensive studies on malaria mosquitoes and their control in Florida, the Caribbean area, and India were also conducted. In diphtheria, the antigenic properties of avirulent bacilli were studied and the identity of the toxin of mitis and gravis strains was established. The work in scarlet fever consisted of the analysis of the studies of strains of hemolytic streptococci causing the disease in Roumania and other parts of the world. In tuberculosis, a study of vaccination in Jamaica using heat killed bacilli was completed showing some apparent degree of protection. The epidemiological study in Williamson County, Tenn., was also continued with emphasis on family transmission, and a study of pulmonary calcification. In the field of nutrition, studies were continued in rural areas of Tennessee, North Carolina, England and Spain, and were extended into Mississippi and Canada.

Aid to state and local health services was given in North Carolina, Mississippi, New York City, and a number of provinces in Canada. Certain Latin American countries and China also received aid in their public health programs.

The schools of public health receiving assistance included those of the University of Michigan, Johns Hopkins, Harvard, Toronto, Sao Paulo, and the National Institute of Health of China. Schools of nursing which received assistance included those of Skidmore College, Venezuela, Panama, Sao Paulo, Brazil, and Lisbon, Portugal.

The Division granted 135 fellowships and training grants to public health personnel chiefly from Latin America.

This brief review indicates the wide range of activities of this most valuable international agency. Although much of its activity has been directed toward the war effort, many constructive peace-

time programs have been continued and initiated. The expenditures totalling over \$2,300,000 were about equal to those in previous years.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

First on Your Reading List— Last fall a commission undertook a clinical trial of inactivated vaccine of influenza virus A and B, upon 12,500 army S. P. T.'s—a highly stable population. Vaccination performed just before or even after the onset of the epidemic protected at a ratio of 3.2 to 1 over the controls. (In some of the units the ratio was 5 or 6 to 1.) The effect of the vaccine becomes evident in about a week but the duration of the protective values has not been determined. More findings are promised.

ANON. A Clinical Evaluation of Vaccination Against Influenza. *J.A.M.A.* 124, 14: 982 (Apr. 1), 1944.

V. D. Case Finding Is War Work—Where generalized public health nurses have been permitted to participate in the venereal disease case finding program, they have been successful, asserts this competent commentator.

BURKE, M. A. Improvement of Present Methods for Extrafamilial Contact Tracing. *Ven. Dis. Inform.* 25, 1:9 (Jan.), 1944.

How to Delouse a Town—There is this much to be offered to the credit of conscientious objectors: these men allowed themselves to be infested with body lice in order that the effectiveness of certain insecticides might be tested. Myself, I'd rather take my chances against the lower but pleasanter vermin—the Japs.

DAVIS, W. A., and WHEELER, C. M. The Use of Insecticides on Men Artificially Infested with Body Lice, (and) DAVIS, W. A., *et al.* Studies on Louse Control in a Civilian Population. *Am. J. Hyg.* 39, 2:163 (Mar.), 1944.

A Few Words on a Big Subject—It will do you not a bit of harm to

have absorbed a first hand account of the methods used to safeguard the shipyard workers. This paper hits only the very highest spots but it is eminently readable.

DRINKER, P. Shipyard Health Problems. *J. Indust. Hyg. & Toxicol.* 26, 3:86 (Mar.), 1944.

For the Drowned—Preferred by the British Navy to the Schaeffer method is rocking. Ankles and wrists of the victim are lashed to the four corners of a stretcher placed over a horse. This see-saw is rocked ten times a minute until breathing commences or until everyone gives up. The Schaeffer method is put into action until the mechanism can be assembled.

EVY, F. C. Resuscitation of the Drowned Today. *J.A.M.A.* 124, 14:964 (Apr. 1), 1944.

With Not a Blow Below the Belt—Every single one of us—without exception—should read these two outstanding papers pro and con the adoption of a compulsory medical prepayment plan. Both addresses are singularly, and happily, free of Billingsgate. Both give off a bright light with a minimum of heat. Would to God all discussers of this question might learn to argue with as much cogency and courtesy!

FALK, I. S. Proposed Extension of the Social Security Program, with Special Reference to Health and Medical Aspects, (and) FAXON, N. W. The Blue Cross, the Blue Shield, and the Wagner-Murray-Dingell Bill. *New Eng. J. Med.* 230, 9:244 (Mar. 2), 1944.

One Hundred and Seventy-two Different Diseases—Exhibit A of the bewildering variety achieved by our several and sovereign states in the mat-

ter of reportable disease. The exhibit has to be seen to be believed: three require the reporting of colds and one each are listed as calling for bronchitis, diabetes, heat prostration, or milk sickness reports.

FOWLER, W. The Reportable Diseases. Pub. Health Rep. 59, 10:317 (Mar. 10), 1944.

Good for Your Soul—This wholesome dissertation on how little we really know when we talk glibly about virus pneumonias should be taken to heart by us all. Atypical pneumonia is not due to a virus, but may be due to any of a variety of causes. The paper closes with the pointed reminder that bacterial pneumonias still exist and measures for their detection should not be neglected.

FRANCIS, T., JR. Virus Pneumonia. Canad. Pub. Health J. 35, 2:49 (Feb.), 1944.

State-wide Mosquito Survey : How Long Since?—In Massachusetts there have been several malaria peaks. One was associated with the returning Union Soldiers after the Civil War. During the not-so-gay 90's the Spanish-war veterans brought back a new crop from Florida and Cuba. During the first 40 years of this century there have been sporadic outbreaks though the level of reports remained low: since 1941 there has been an increase. What may happen in this and other northern states when our army returns from all the malarious regions of the earth is anybody's pessimistic guess.

GETTING, V. A. Malaria in Massachusetts. New Eng. J. Med. 230, 12:350 (Mar. 23), 1944.

Estimating Caries Prevalence—Having the kind of mind that goes blank at the first glimpse of a formula involving the square root of $p d q$ over $b v d$, I can report here only that this paper seems to be the kind that should be read by anyone who proposes to think about, or discuss, or do something about the problem of dental caries.

KNUTSON, J. W. An Index of the Prevalence of Dental Caries in School Children. Pub. Health Rep. 59, 8:253 (Feb. 25), 1944.

War-Working Women—Here are four good papers on specific hygienic problems posed by the large scale influx of women into industry, a series which will prove useful to health workers who may be directly or even remotely concerned with industrial health.

KRONENBERG, M. H. Working Conditions for Female Employees (and three related papers). J.A.M.A. 124, 11:677 (Mar. 11), 1944.

Chiefly for the Internationally Minded—Some of the reasons why the health organization of the late League of Nations failed to tick in the hearty manner its originators hoped for are recounted in this introduction to a dissertation upon future international public health administrative possibilities.

MACKENZIE, M. D. A Study of the Potentialities of International Collaboration in Medicine in the Post-War World. J. Roy. Inst. Pub. Health & Hyg. 7, 3:66 (Mar.), 1944.

North of the Border—If and when (Canadian) health insurance becomes operative, prognosticates this health official, public health will have received a most encouraging stimulus. He gives the reasons for his belief.

MCCANN, J. J. Health Insurance from the Public Health Standpoint. Canad. Pub. Health J. 35, 2:59 (Feb.), 1944.

How Many Medicos?—Counting medical noses is not the best way of estimating available medical resources, says this writer. Though physicians seldom formally retire until they have achieved an advanced age, the number of patients a physician sees declines steadily after age 40. A series of formulae are offered for measuring physician resources of a community.

PENNELL, E. H. Location and Movement of Physicians—Methods for Estimating Physician Resources. Pub. Health Rep. 59, 9:281 (Mar. 3), 1944.

Have You Seen Influenza B?—Seven researchers, aided and abetted by seven different benefactors, studied the influenza B virus and obtained some outstanding electron micrographs which reveal certain differences between that virus and influenza A. They learned a lot more about influenza B, which you can add to your store of knowledge by reading the paper.

SHARP, D. G., *et al.* Isolation and Characterization of Influenza Virus B (Lee Strain). *J. Immunol.* 48, 2:129 (Feb.), 1944.

New and Quite Russian—Do you know what a phytoncide is? A phytoncide is a volatile substance produced by plants, and having bactericidal and protistocidal properties. Freshly macerated onion or garlic gives off phytoncidal fumes which will kill yeast cultures and frog's eggs—among other living things. Now that you have been let into the secret, you'll have to read four papers to learn about the practical ap-

plications of this phenomenon, or you can turn to *Time* magazine—43, 11:40 (Mar. 13), 1944—for a curt, clear, and concise account.

TOKIN, B. Effect of Phytoncides upon Protozoa, (and) KOVALENOK, A. Action of Phytoncides upon Infusoria, (and) TOROPTSEV, I. Effect of Phytoncides upon Rabbits, (and) The Use of Phytoncides in the Treatment of Infected Wounds. *Am. Rev. Soviet Med.* 1, 3:237 (Feb.), 1944.

Planned Hunger—Though it may give you a case of the creeping meemies, you should read this account of the dreadful "disease of starvation" which decimated the refugee camps of Spaniards in unoccupied France. The daily diet of 1,100 calories was derived chiefly from pumpkins, cabbage, and carrots.

ZIMMER, R., *et al.* The Nutritional Situation in the Camps of the Unoccupied Zone of France in 1941 and 1942 and Its Consequences. *New Eng. J. Med.* 230, 11:304 (Mar. 16), 1944.

ASSOCIATION NEWS

SECOND WARTIME PUBLIC HEALTH CONFERENCE AND SEVENTY-THIRD ANNUAL BUSINESS MEETING AMERICAN PUBLIC HEALTH ASSOCIATION

New York, N. Y., October 3-5, 1944

Headquarters: Hotel Pennsylvania

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Howard S. Allen, M.D., Main St., Woodbury, Conn., Health Officer

Robert J. Anderson, M.D., 311 S. Juniper St., Philadelphia 7, Pa., P.A. Surgeon, U. S. Public Health Service

Morton H. Aronsohn, M.D., 1471 Taylor Ave., New York 60, N. Y., Tuberculosis Clinician, Dept. of Health

Clarence Barth, M.D., 26 West St., Newburgh, N. Y., Health Officer

J. Howard Beard, Jr., M.D., Wilkinson County Health Dept., Woodville, Miss., Director

Juan A. Borrelli, M.D., M.P.H., Yaguaron 1835, Montevideo, Uruguay, S. A., Lieutenant, Army of Uruguay

Hugh Brewster, M.D., 114 Pike, Port Jervis, N. Y., Health Officer

Glidden L. Brooks, M.D., 2827 Garland Ave., Muskogee, Okla., Director, City-County Health Dept.

H. Russell Brown, M.D., Citizens National Bank Bldg., Watertown, S. D., Superintendent, Codington County Board of Health

John M. Butler, M.D., Black Hills Clinic, Hot Springs, S. D., City Physician and Vice-President, County Board of Health

Cassius C. Carter, M.D., Box 2599, Juneau, Alaska, Commissioner of Health, Territory of Alaska

Ward L. Chadwick, M.D., Denver General Hospital, Denver 4, Colo., Surgeon (R), U. S. Public Health Service

Bryson E. Cox, M.D., 223 N. 5th St., Coalinga, Calif., Physician and Surgeon

Walter E. Cox, M.D., P. O. Box 357, Angleton, Tex., Director, Brazoria County Health Unit

John E. Curtis, M.D., County Board of Health, Lemmon, S. D., Superintendent

Thomas S. Davies, M.D., 279 Rivard Blvd., Grosse Pointe, Mich., Health Commissioner

Richard L. DeSaussure, M.D., 3712 R St., N.W., Washington 7, D. C., Medical Director, Southwest Health Center

William Duncan, M.D., 809 W. 1st St., Webster, S. D., Superintendent, Day County Board of Health

Harrison Eilers, M.D., M.P.H., Box 360, San Luis Obispo, Calif., County Health Officer

Vern W. Embree, M.D., Sully County Board of Health, Onida, S. D., Superintendent

Armando M. Gamboa, M.D., 11 Clearwater Rd., Chestnut Hill 67, Mass., P.A. Surgeon (R), U. S. Public Health Service

Edward E. Hamer, M.D., State Board of Health, Carson City, Nev., State Health Officer

Lyle Hare, M.D., State Board of Health, Spearfish, S. D., Member

G. L. Hickman, M.D., Hill St., Bryant, S. D., Superintendent, Hamlin County Board of Health

A. Joseph Hughes, M.D., 3rd and Cooper Sts., Helen Apts., Camden, N. J., P.A. Surgeon, U. S. Public Health Service

Philip Joseph, M.D., 7½ N. Park, Sapulpa, Okla., Director, Creek County Health Dept.

- Edward P. Kemp, M.D., 178 Reef Rd., Fairfield, Conn., Health Officer
- Manly F. Langston, M.D., M.P.H., 203 Old Post Office Bldg., Chattanooga, Tenn., Chief, Local Health and Safety Services, Tennessee Valley Authority
- J. P. MacDowell, M.D., 27 Harpending Ave., Dundee, N. Y., Health Officer
- John N. Mangieri, M.D., Bangall, N. Y., Health Officer of Clinton and Stanford
- Arthur D. Marsh, M.D., Hampton, Conn., Health Officer
- R. H. Mayes, M.D., 130 W. 22nd, Ada, Okla., Director, Pontotoc County Health Dept.
- William L. Meyer, M.D., S. D. State Sanatorium for Tuberculosis, Sanator, S. D., Superintendent
- Stephen Monteith, 75 N. Broadway, Nyack, N. Y., Health Officer
- Eli M. Morehouse, M.D., Box 214, Yankton, S. D., Superintendent, Yankton County Board of Health
- Sherburne F. Morgan, M.D., 6336 N. Berkeley Blvd., Milwaukee, Wis., Health Commissioner, Village of Whitefish Bay
- Edwyn W. O'Dowd, M.D., Old Tappan Rd., Tappan, N. Y., Health Officer, Town of Orangetown
- Capt. Frederick A. Olson, M.C., Med. Det. 363 Inf., Camp Adair, Ore.
- Robert T. Potter, M.D., Johns Hopkins School of Hygiene and Public Health, Baltimore 5, Md., Asst. Surgeon, U. S. Public Health Service
- Roy S. Pruitt, Room 1007, New Federal Bldg., St. Louis 1, Mo., Chief, St. Louis Station, Food and Drug Admin.
- Junius M. Rawlings, M.D., 4700 Hastings St., El Paso, Tex., Traveling Representative, Pan American Sanitary Bureau
- A. P. Reding, M.D., Turner County Health Dept., Marion, S. D., Asst. County Health Officer
- Michael D. Riordan, M.D., 59 Church St., Willimantic, Conn., Health Officer, Town of Windham
- Howard L. Saylor, M.D., 752 Kas. S. E., Huron, S. D., Superintendent, Beadle County Board of Health
- Everett E. Scott, Houston, Mo., Texas County Sanitarian
- Mary N. Stephenson, M.A., State Capitol Annex, Denver, Colo., State Director of Public Assistance, State Dept. of Public Welfare
- Frederick D. Stubbs, M.D., Health Center, 20th & Berks St., Philadelphia, Pa., Administrator, Philadelphia Health Center
- Edward F. Timmins, M.D., 527 Broadway, South Boston, Mass., Medical Inspector, Boston Health Dept.
- Edwin F. Trautman, M.D., 5385 Main St., Bridgeport 14, Conn., Health Officer, Township of Monroe
- Harold C. Waddel, D.O., 537 Kinderkamack Rd., Oradell, N. J., Health Officer, New Milford Board of Health
- Ernest A. Wilkinson, M.D., Hyde County Board of Health, Highmore, S. D., President
- John A. Wolcott, 248 Seneca St., Oil City, Pa., Health Officer
- Thomas V. Woodring, M.D., City Health Dept., Nashville, Tenn., Director of Health
- J. R. Wright, M.D., Dept. of Health, Las Vegas, N. M., Acting District Health Officer

Laboratory Section

- Gayle Beeswy, The Upjohn Co. 33, Kalamazoo, Mich., Bacteriologist
- Harry Belmar, D.V.M., 1032 Woodland Drive, Dothan, Ala., Food Sanitation Officer, Houston County Health Dept.
- Corp. Charles H. Benckert, Med. Det., Station Hospital, Patterson Field, Ohio
- Margareth Cole, 5151 N. Capitol Ave., Indianapolis 8, Ind., Bacteriologist, Pitman-Moore Co.
- Lt. Gabriel W. Comita, M.C., Station Hospital, Fort Rodman, New Bedford, Mass., Post Sanitary Officer
- Ruth F. Curry, 45 Council St., Tucson, Ariz., Senior Bacteriologist, Arizona State Laboratory
- Charles H. Drake, Ph.D., 523 Snow Hall, Univ. of Kansas, Lawrence, Kans., Instructor in Bacteriology
- Ernest C. Fowler, 797 Central Ave., Wyandotte, Mich., Chief Chemist, Wayne County Road Commission
- Nathan Gallenson, 926 E. South Temple St., Salt Lake City 2, Utah, Senior Bacteriologist, State Dept. of Health
- Dorothy A. Hurley, 73 Rogers Ave., Somerville, Mass., Bacteriologist, Skinner & Sherman, Inc.
- John G. Heemstra, State Health Laboratory, Vermillion, S. D., Junior Bacteriologist, State Board of Health
- Charles H. Hoppel, Room 232, City Hall, Cincinnati, Ohio, Bacteriologist, Dept. of Health Laboratories
- Helen H. Jackson, 26 North University St., Vermillion, S. D., Technician, State Health Laboratory
- Comdr. Sheldon A. Jacobson, M.C., 115-26-224th St., St. Albans, L. I., N. Y., Laboratory Officer in Charge, U. S. Naval Hospital
- Daniel M. Jones, 274 S. 1st West, Cedar City, Utah, Bacteriologist, State Dept. of Health
- Charles Lieberman, 1078 Ashland Ave., St. Paul 5, Minn., Chemist, Water Purification Plant

Mary Lockwood, Dean Apt. G105, Lansing, Mich., Bacteriologist, State Dept. of Health
Henry F. Long, Ph.D., 123 N. Washington Ave., Danville, Ill., Bacteriologist, Sugar Creek Creamery Co.

Alma E. Miller, East Moline State Hospital, East Moline, Ill., Bacteriologist, Dept. of Public Welfare

Rudolph W. Newtonson, P. O. Box 1161, Mailuku Maui, T.H., Laboratory Administrator, Board of Health

Enos G. Pray, M.S., 8415 N. Monticello Ave., Skokie, Ill., Head Biologist, Hospital Liquids, Inc.

Isaac H. Pributsky, E. 3rd and Kilgour Sts., Cincinnati 2, Ohio, Asst. Scientific Aide, U. S. Public Health Service

Charles S. Puntney, 325 E. Broadway Ave., East St. Louis, Ill., Director, Branch Laboratory, State Dept. of Public Health

Anne Purcell, Dept. of Bacteriology, State College, Pa., Asst. Bacteriologist, Pennsylvania State College

Erling R. Quortrup, D.V.M., Box 603, Brigham, Utah, Veterinarian, U. S. Fish and Wildlife Service

Bernard J. Schaaf, W. Va. State Hygienic Laboratory, Charleston 5, W. Va., Senior Serologist

Irma Seijo, 70 Grove St., New York 14, N. Y., Senior Medical Technician, Gonococcus Research Unit, Dept. of Health

Carolyn I. Shaw, 45 Grove St., Boston 14, Mass., Junior Bacteriologist, State Dept. of Public Health

Noble P. Sherwood, M.D., 517 Snow Hall, Univ. of Kansas, Lawrence, Kans., Professor of Bacteriology

Roscoe R. Spencer, M.D., National Cancer Institute, Bethesda, Md., Medical Director and Chief, National Cancer Institute, U. S. Public Health Service

Minnie E. Sporer, 209 S.W. 1st Ave., Mineral Wells, Tex., Director of Regional Laboratory, Palo Pinto-Parker County Health Unit

Warren E. Wheeler, M.D., Childrens Hospital of Michigan, Detroit 2, Mich., Director of Laboratories

Vital Statistics Section

E. Anne Amison, P. O. Box 1563, Santa Fe, N. M., Field Agent, Div. of Vital Statistics, State Health Dept.

Major Harold F. Dorn, Sn.C., 15 Burning Tree Court, Bethesda 14, Md., Director, Medical Statistics Division, Office of the Surgeon General, War Dept.

Francisco E. Semidei, M.D., 127 Mallette St., Chapel Hill, N. C., Student, Univ. of North Carolina

Percy W. Weston, 2675 Caddboro Bay Rd.,

Victoria, B. C., Canada, Asst. Director of Vital Statistics, Provincial Board of Health
Lt. Theodore D. Woolsey, U.S.N.R., 111 W. Underwood St., Chevy Chase 15, Md., Assigned to Vital Statistics Section, Division of Preventive Medicine, Bureau of Medicine & Surgery, Navy Dept.

Engineering Section

Paul Agnano, M.C.E., 2000 Massachusetts Ave., N.W., Washington 25, D. C., Asst. Engineer (R), U. S. Public Health Service
C. Theodore Beechwood, V.M.D., 120 State Capitol Bldg., Salt Lake City, Utah, P.A. Sanitarian (R), U. S. Public Health Service
Donald J. Boughton, 725 Third St., Coeur d'Alene, Ida., Sanitarian, Kootenai County Health Unit

Edwin J. Dahl, 505 Everett St., Caldwell, Ida., Sanitarian, State Dept. of Public Health
Capt. Leonard W. Gopp, Sn.C., Station Hospital, Scott Field, Ill., Sanitary Engineer

Robert H. Gray, 613 Harrington St., Wilmington, Del., Dairy Inspector, Wilmington Board of Health

Howard F. Hoffman, 24 Grant St., Utica 3, N. Y., Junior Sanitary Engineer, State Dept. of Health

Keith S. Krause, 2000 Massachusetts Ave., N.W., Washington 14, D. C., Asst. Engineer (R), U. S. Public Health Service

E. Fred Lowe, Jr., M.S., Peninsula Health District, Hampton, Va., Asst. Sanitarian (R), U. S. Public Health Service

Charles A. Mangano, Chippewa County Health Dept., 140 W. Spruce St., Sault Ste. Marie, Mich., Sanitary Officer

Wallace T. Mills, State Dept. of Health, Hondo Tex., Sanitarian

H. M. Pierce, 409 Third St., S.W., Huron, S. D., City Engineer

Charles H. Riggs, 847 W. Jefferson St., Franklin, Ind., Water Works Supervisor, Camp Atterbury

G. A. Scrimshire, P. O. Box 517, Uvalde, Tex., Sanitarian, Southwestern Texas Health Unit

Laurent Thauvette, Health Unit, Amos, Abitibi, Quebec, Canada, Consulting Engineer

Major Leslie West, Sn.C., 118 S. Kingman Rd., South Orange, N. J., Instructor in Military Sanitation, Medical Field Service School

Walter A. White, 491 Main St., Saco, Me., District Sanitary Engineer, State Bureau of Health

Industrial Hygiene Section

Dr. Salvador Gomez-Alvarez, Av. Juarez 579, Guadalajara, Jal., Mexico, Director of Tuberculosis Dept., S.P.M. Hospital

A. Link Koven, M.D., State Board of Health,

Jefferson City, Mo., Industrial Hygiene Physician
 Capt. Stanley R. Parkinson, M.C., 15th & Clay Sts., Oakland 4, Calif.
 Aloysius M. Stang, 447 Biddle Ave., Pittsburgh 21, Pa., Industrial Hygiene Engineer, State Dept. of Health
 M. Grace Watson, State Dept. of Health, Smith Tower, Seattle 4, Wash., Industrial Advisory Nurse

Food and Nutrition Section

George K. Anderson, M.D., 535 N. Dearborn St., Chicago 10, Ill., Secretary, Council on Foods and Nutrition, American Medical Assn.
 Jane M. Diehm, M.S., 12337 Cedar Rd., Cleveland Heights 6, Ohio, Asst. Nutritionist, Cleveland Health Council
 William J. Guerin, 6542 S. Fairfield Ave., Chicago 29, Ill., Chief Sanitary Officer, Chicago Health Dept.
 Doris M. Hartson, 212 N. Third St., Harrisburg, Pa., Staff Nutritionist, State Health Dept., Bureau of Industrial Hygiene
 Howard K. Johnston, Ph.D., City Health Dept., Sioux Falls, S. D., Asst. Sanitarian (R), U. S. Public Health Service
 Marion K. Meter, 370 Commonwealth Ave., Boston, Mass., Student, Harvard Univ.
 George F. Reeves, Room 64, Municipal Courts Bldg., St. Louis, Mo., Supervisor, Food Inspection Service, Health Dept.
 Robert W. Wilson, Jr., 8905 E. Jefferson Ave., Detroit, Mich., Vice-President, Frederick Stearns & Co.

Maternal and Child Health Section

Amy Breyer, M.D., Station A, Drawer K, Hartford, Conn., Physician, Div. of Crippled Children, State Dept. of Health
 Caroline A. Chandler, M.D., Children's Bureau, Dept. of Labor, Washington 25, D. C., Specialist in Child Hygiene
 Paul W. Emerson, M.D., 422 E. 19th St., Cheyenne, Wyo., Director, Div. of Maternal and Child Health & Crippled Children, State Health Dept.
 Charles A. Gordon, M.D., 32 Remsen St., Brooklyn, N. Y., Professor of Clinical Obstetrics and Gynecology, Long Island College of Medicine
 Catherine Henes, M.S., 1 Chapin Ave., West Roxbury 32, Mass., Public Health Social Work Supervisor, State Dept. of Public Health
 William V. Holt, M.D., Crompond Road, Yorktown Heights, N. Y., Physician
 Frederic M. Kriete, M.D., 2971 Kenwood St., Salt Lake City, Utah, Pediatric Consultant,

Div. of Maternal and Child Health, State Dept. of Health
 Charles Newberger, M.D., 5038 Drexel Blvd., Chicago 15, Ill., Consultant in Maternity and Infancy, State Dept. of Public Health
 Jannice Rafuse, 73 Tremont St., Boston, Mass., Child Health Consultant, Div. of Child Hygiene, State Dept. of Public Health
 Helen L. Roberts, M.D., 25 Berkshire Rd., Newtonville 60, Mass., Student, Harvard School of Public Health
 Stuart S. Stevenson, M.D., 388 Old Post Rd., Fairfield, Conn., Instructor in Child Health, Harvard School of Public Health
 Franziska Weiss, M.D., Harvard School of Public Health, 55 Shattuck St., Boston, Mass., Student

Public Health Education Section

Ruby F. Anderson, 1997 Scenic Ave., Martinez, Calif., School Nurse, Concord Grammar School
 Verna E. Barkley, R.N., 4 Maple Rd., Prospect, Pa., Exec. Sec., Butler County Tuberculosis and Public Health Society
 Berl ben Meyr, 116 Temple St., Los Angeles 12, Calif., Sanitation Inspector, City Health Dept.
 Jay I. Boxer, M.A., Room 607 Loew Bldg., Syracuse 10, N. Y., Community Health Educator, Onondaga Health Assn.
 Roger DeBusk, M.D., 2650 Ridge Ave., Evanston, Ill., Exec. Director, Evanston Hospital Assn.
 C. E. DeCamp, D.V.M., Post Rd., at Maple St., Scarsdale, N. Y., Veterinarian
 Marvin W. Dehn, City Hall, Grand Forks, N. D., City Dairy and Food Inspector
 Julia B. Dimond, 312 W. Laurel, Visalia, Calif., Exec. Sec., Tulare County Tuberculosis Assn.
 Charles L. Freeman, A.M., Elks Club, Springfield, Ill., State Director, National Foundation for Infantile Paralysis, Inc.
 W. George Gould, M.A., 115 Hudson St., East Keansburg, N. J., Asst. Director, Div. of Legal and Protective Services; American Social Hygiene Assn.
 Edna M. Hoffa, R.N., Tuberculosis Society of Lancaster County, 600 Juliette Ave., Lancaster, Pa., Exec. Sec.
 Mary M. Hurley, 56 Charlesgate East, Boston 15, Mass., Student, Harvard School of Public Health
 Alma M. Jackson, M.S., 1102 E. Ann St., Ann Arbor, Mich., Student, Univ. of Michigan
 William R. Lenderking, 912 Chanin Bldg., 122 E. 42nd St., New York 17, N. Y., Vice-President, Lily Tulip Cup Corp.
 Lillian L. Long, R.N., P. O. Box 247, Somers-

- set, Pa., Exec. Sec., Somerset County Tuberculosis Society
- Hugh B. Masters, M.A., 258 Champion St., Battle Creek, Mich., Educational Director, W. K. Kellogg Foundation
- Marjorie B. May, 14 Metropolitan Oval, New York 62, N. Y., Asst. in Health Education, Dept. of Health
- L. L. McKee, 529 Cherry St., Gadsden, Ala., Food Inspector, Etowak County Health Dept.
- Lillian G. Meade, 1729 27th St., W., Birmingham 8, Ala., State Commander, Women's Field Army, American Society for the Control of Cancer
- John B. Middleton, M.A., 1137 E. Jersey St., Elizabeth 4, N. J., State Director, National Foundation for Infantile Paralysis, Inc.
- John J. Naughton, V.M.D., 1623 Clay Ave., Scranton, Pa., Asst. Director, Quality Control, Dairymen's League
- Charles S. Nelson, 79 E. State St., Columbus 15, Ohio, Exec. Sec., Ohio State Medical Assn.
- John D. Porterfield, M.D., 615 N. Wolfe St., Baltimore 5, Md., P.A. Surgeon, U. S. Public Health Service
- Aida M. Rivera, Reina St., 118, Ponce, Puerto Rico
- Laura Robinson, R.N., M.A., Paterson General Hospital, Paterson 3, N. J., Superintendent of Nurses
- Silvester N. Scherer, 2700 Hillside Drive, Burlingame, Calif., Director of Publicity, California Tuberculosis Assn.
- Lloyd B. Sharp, Ph.D., 14 W. 49th, Room 806, New York, N. Y., Exec. Director, Life Camps, Inc.

NATIONAL HEALTH HONOR ROLL AWARDS FOR 1943

Fifty-three communities have been granted awards in the National Health Honor Roll for 1943, according to a recent announcement by the sponsoring agencies, the United States Chamber of Commerce and the American Public Health Association. This recognition for progress in community health protection has been made on the basis of *Evaluation Schedules* submitted during March and April, 1944, and covering the various health activities throughout the year 1943.

The cities which attained the 1943 National Health Honor Roll are:

Baltimore, Md.
Detroit, Mich.
Evanston, Ill.
Greenwich, Conn.
Hackensack, N. J.
Hartford, Conn.
Houston, Tex.
Jackson, Mich.
La Salle-Peru-Oglesby, Ill.
Little Rock, Ark.
Madison, Wis.

Milwaukee, Wis.
Newark, N. J.
Newton, Mass.
Pasadena, Calif.
Peoria, Ill.
Racine, Wis.
Reading, Pa.
Rochester, Minn.
San Jose, Calif.
Schenectady, N. Y.
Stamford, Conn.

The counties which attained the 1943 National Health Honor Roll are:

Allegan County, Mich.
Arlington County, Va.
Austin-Travis County, Tex.
Barry County, Mich.
Calhoun County, Mich.
Coahoma County, Miss.
Davidson County, Tenn.
Dickinson County, Mich.
Eaton County, Mich.
El Paso City-County, Tex.
Fayette County, Ky.
Forsyth County, N. C.
Gibson County, Tenn.
Glynn County, Ga.
Ingham County, Mich.
Jackson County, Ore.

Jones County, Miss.
Lauderdale County, Miss.
Leflore County, Miss.
Los Angeles County, Calif.
Louisville-Jefferson County, Ky.
Madison County, Ky.
Mason County, Mich.
Memphis-Shelby County, Tenn.
Menominee County, Mich.
Midland County, Mich.
Saginaw County, Mich.
Santa Barbara County, Calif.
Spartanburg County, S. C.
Van Buren County, Mich.
Washington County, Miss.

Appropriate plaques will be forwarded to the communities shortly after June 1. Prior to this date interpretative letters discussing the details of individual programs will be forwarded to each community. The cancellation of the 1944 annual meeting of the United States Chamber of Commerce, scheduled originally for the first week of May, has necessitated a change in the usual custom of presenting the awards on this occasion. The American Public Health Association will give public recognition to the winning communities at the annual meeting in New York City the first week in October.

Evaluation Schedules showing the annual health inventory for 1943 were received from 190 communities.

The National Health Honor Roll is financed jointly by the W. K. Kellogg Foundation and the Metropolitan Life Insurance Company.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York 19, N. Y.

POSITIONS AVAILABLE

NEWS FROM THE FIELD

UNIVERSITY OF MICHIGAN INSTITUTE ON DENTAL HEALTH ECONOMICS

The School of Public Health of the University of Michigan has announced plans for an Institute on Dental Health Economics to be held at Ann Arbor throughout the week of June 26 to July 1.

It is the purpose of this Institute to bring together a group of outstanding leaders in the field of dental health under the chairmanship of Dr. Kenneth A. Easlick, Associate Professor of Public Health Dentistry, in order that they may share their experiences and pool their thoughts on the improvement of the dental health of the American people. It is planned to review briefly the social and economic background of health problems, and against this setting to develop a comprehensive understanding of the dental problem. Minimum standards of dental health service will be considered and concise information will be presented to assist in the development of a program to solve the dental problem at this level of standards. It is intended that the work of the Institute will culminate in concrete proposals for a dental health program designed to meet the challenging needs which are known to exist.

The following are among the speakers who will participate in the formal program:

- R. C. Williams, M.D., Director, Division of Medical Services, U. S. Public Health Service
- John W. Knutson, Dental Surgeon, U. S. Public Health Service
- Henry Klein, Senior Dental Officer, U. S. Public Health Service
- Nathan Sinai, Dr.P.H., Professor of Public Health, University of Michigan
- Harold Y. McClusky, Ph.D., Professor of Educational Psychology, University of Michigan
- Melvin L. Dollar, Public Health Economics, University of Michigan

Marcus L. Ward, D.D.S., Jonathan Taft Professor of Dentistry, University of Michigan

Don W. Gullett, D.D.S., Secretary, Canadian Dental Association

Harold Hillenbrand, D.D.S., Associate Editor, *Journal of the American Dental Association*

John Oppie McCall, D.D.S., Director, Guggenheim Dental Clinic, New York, N. Y.

John T. O'Rourke, D.D.S., Dean, School of Dentistry, University of Louisville

Walter H. Philips, D.D.S., Director, Dental Division, Detroit Department of Public Welfare

R. M. Walls, D.D.S., Member of Committee on Economics, American Dental Association

J. M. Wisan, D.D.S., Director, Dental Health Division, New Jersey State Department of Health

Because of the nature and purpose of the Institute registration must be limited to fifty members. Although an attempt will be made to obtain a geographic distribution of the applicants, primary consideration will be given to the order in which applications are received. The registration fee will be \$10. Requests for application blanks should be sent promptly to Dr. Kenneth A. Easlick, School of Public Health, Ann Arbor, Mich.

MEETING ON PUBLIC HEALTH BROADCASTS

The Institute for Education by Radio has been held annually for fourteen years under the auspices of Ohio State University. Last year for the first time a meeting on the subject of public health broadcasts was included. David Resnick, Director of Public Relations of the National Society for the Prevention of Blindness, presided and among the participants were Daniel C. McCarthy, of the National Tuberculosis Association, Dr. E. R. Coffey, U. S. Public Health Service, Thomas C. Edwards, Office of the Coördinator of Inter-American

Affairs, Dr. Iago Galdston, New York Academy of Medicine, Dr. Robert G. Paterson, Ohio Public Health Association, and Muriel Steward, Hennepin County Tuberculosis Association. Now it is announced that another section meeting on public health broadcasts will be part of the Fifteenth Institute for Education by Radio, to be held in Columbus, Ohio, May 5-8. This session is scheduled for Saturday evening, May 6. Mr. Resnick is Chairman and Dr. Coffey is discussion leader. Directors of health education from governmental and voluntary health agencies and executives of broadcasting networks and local radio stations will participate in the discussions.

DR. PARRAN REAPPOINTED SURGEON GENERAL

Upon nomination by President Roosevelt, Thomas Parran, M.D., who for eight years has been Surgeon General of the U. S. Public Health Service, was recently nominated for a third term of four years and was immediately confirmed by the Senate.

CHILDREN'S BUREAU COMMISSION ON CHILDREN IN WARTIME

Ruth Houlton, R.N., Director of the National Organization for Public Health Nursing represented the American Public Health Association at the meetings of the Children's Bureau Commission on Children in Wartime on March 17 and 18 in the absence of Dr. Atwater, and reports as follows:

The Children's Bureau Commission on Children in Wartime appointed by Katherine Lenroot, Chief of the Children's Bureau, in February, 1942, when it met to adopt A Children's Charter in Wartime met again in Washington, D. C., on March 17 and 18, to review its activities and to consider goals for the future.

A large proportion of the more than 75 members of the Commission repre-

senting many official and voluntary agencies interested in the health and welfare of children attended the meeting, and participated in the discussion. Physician, dentist and nurse members of the Commission include:

Fred L. Adair, M.D., American Committee on Maternal Welfare
 Frederick H. Allen, M.D., Philadelphia Child Guidance Clinic
 Reginald M. Atwater, M.D., American Public Health Association
 Leona Baumgartner, M.D., New York City Department of Health
 Alice Drew Chenoweth, M.D., Kentucky State Department of Health
 Paul B. Cornely, M.D., Howard University, Washington, D. C.
 Nicholson J. Eastman, M.D., Johns Hopkins Hospital
 Franklin P. Gengenbach, M.D., President, American Academy of Pediatrics
 Henry F. Helmholz, M.D., The Mayo Clinic
 Ruth Houlton, R.N., National Organization for Public Health Nursing
 Emory W. Morris, D.D.S., W. K. Kellogg Foundation
 Ellen C. Potter M.D., New Jersey State Department of Institutions and Agencies
 Mabel K. Staupers, R.N., National Association Colored Graduate Nurses
 George S. Stevenson, M.D., National Committee for Mental Hygiene
 Felix Underwood, M.D., State Health Officer, Mississippi

Leonard W. Mayo, Dean, School of Applied Social Sciences, Western Reserve University, was reelected Chairman.

An interesting feature of the meeting was a panel of 12 boys and girls who discussed, "Next Steps in Planning for Children and Youth." The discussion leader was C. B. Loomis, head, Department of Sociology, Piedmont College, Georgia. Participants came from all parts of the country and included college and high school students as well as workers in textile and defense industries. Among them were a Chinese girl and a Negro boy and girl. In the President's Proclamation of May 1 as Child Health Day, youth forums of this kind are encouraged.

The "Goals for the Future as We Go from War to Peace" adopted by the Commission include the following emphases on health:

Extension of health service and medical care to assure access to adequate care for all mothers and children

Regulation of child labor and safeguarding of youth in wartime employment

Safeguarding family life in wartime during demobilization and in the post-war period

Review and revision of legislative safeguards and standards relating to children in preparation for the 1945 sessions of the legislatures, in the light of these goals for children

Sharing of the public responsibility for the health, education, and welfare of children by federal, state, and local authorities, with recognition of the primary responsibility of the state and local units, the importance of providing federal funds for local services through grants-in-aid to appropriate State agencies, and with the removal of residence restrictions in the selection of personnel for such programs

Provision for the training of professional personnel required for services for children and youth and for the preparation of volunteers to assist in rendering such services

Increased opportunities for youth to share in the planning and development of programs—local, state, and national, and international—for the benefit of youth

Education of parents, youth, and all citizens concerning the importance of providing full security and opportunity for children for the sake of their own happiness and well-being and for the future of the nation

U. S. PUBLIC HEALTH SERVICE REORGANIZES THE INDUSTRIAL HYGIENE DIVISION

The reorganization of the Public Health Service effected by action of the 78th Congress became operative on December 30, 1943. Under the new plan of administration, the present structure of the Industrial Hygiene Division, with the exception of the Research Section, becomes a Division of the Bureau of State Services. The Research Section remains in the National Institute of Health and will be known as the Industrial Research Laboratory.

Medical Director J. G. Townsend, who heads the Division, has announced the following personnel in charge of the Sections and Units which comprise the reorganized Industrial Hygiene Division:

Dermatoses Section (formerly the Dermatoses Investigation Section)—Medical Director Louis Schwartz

Field Operations Section (formerly the States Relations Section)—Senior Sanitary Engineer J. J. Bloomfield

Medical Unit—Surgeon W. C. Dreessen

Engineering Unit—Sanitary Engineer (R) Harry E. Seifert

Statistical Unit—Principal Statistician W. M. Gafafer

Chemical Unit—Senior Chemist F. H. Goldman

INTERNSHIPS IN PUBLIC HEALTH

The following announcement is quoted from the issue of *New York State Health News* for March 6:

"The State Department of Health will consider applications from young physicians interested in securing training in the field of public health. Applicants must possess certain basic qualifications among which are United States citizenship, graduation from a medical school approved by the American Medical Association, and license to practise medicine in New York State or eligibility to take the examination to obtain such a license.

"The training consists of 6 to 12 months' field experience followed by an academic year at a postgraduate school of public health.

"Physicians interested in this training should write to the State Department of Health, Albany 1, N. Y., or communicate with the nearest district state health officer. If the applicant desires to attend school this fall, his field training must begin in the near future. Immediate application is advised."

MT. SINAI HOSPITAL PLANS POST-WAR EXPANSION

Mt. Sinai Hospital, New York, N. Y.,

has announced the appointment of George Baehr, M.D., who recently has served as chief medical officer of the Office of Civilian Defense, and as Medical Director in the U. S. Public Health Service (R), as Director of Clinical Research. He will coördinate the hospital's clinical research activities, the work of the laboratories, and the development of the use of the hospital's facilities.

Isidore Snapper, M.D., formerly of Amsterdam, Netherlands, and Peking, China, was appointed director of graduate medical education for the hospital.

PUERTO RICO PUBLIC HEALTH ASSOCIATION

At its Annual Meeting held in February, the Puerto Rico Public Health Association elected the following new officers:

President—Oscar Costa-Mandry, M.D.

President-elect—Jose N. Gandara, M.D.

Vice-President—Ezequiel Martinez-Rivera, M.D., M.S.P.H.

Secretary—Guillermo Arbona, M.D., M.P.H.

Treasurer—Celia Guzman, R.N., M.A.

Representative to A.P.H.A. Governing

Council—Pablo Morales Otero, M.D.

PERSONALS

Central States

JOHN K. ALTLAND, M.D., M.S.P.H.,† Hastings, Mich., was to resume his position as Director of the Barry County Health Department on March 16.

JAMES A. CAMPBELL, M.D., Health Director of Scott County, Kan., has been appointed to a similar position in Mason County.

B. RUSSELL FRANKLIN, C.P.H.,† Chief Sanitarian of the Lorain County District Department of Health, Oberlin, Ohio, has been granted a leave of absence for the duration to accept a commission as Lieutenant (jg) in the U. S. Navy.

FRED H. RHODES, M.D., has been appointed Health Officer of Washington County, Kan.

ORLIN P. WOOD, M.D., Marysville, Kan., has been appointed Health Officer of Marshall County.

RALPH W. G. WYCKOFF, PH.D.,† has recently joined the staff of the University of Michigan School of Public Health, Ann Arbor, Mich., to work in the virus laboratory on biophysical methods.

Eastern States

L. VAND. CHANDLER,* Health Officer of Hackensack, N. J., was recently cited by the Hackensack Chamber of Commerce for his work as Chairman of the Permanent War Finance Committee during the 4th War Loan campaign. According to the announcement, Mr. Chandler through his own efforts sold \$530,000 in War Loan Bonds.

N. STANLEY LINCOLN, M.D.,† who has been Superintendent of the Mt. Morris Tuberculosis Hospital, Mt. Morris, N. Y., for the past 9 years, has been transferred by the Division of Tuberculosis of the New York State Department of Health to the position of Superintendent of the Hermann M. Biggs Memorial Hospital, Ithaca, N. Y., succeeding JOHN K. DEEGAN, M.D.,† who resigned to enter military service.

JANICE RAFUSE, M.D.,† is now a member of the staff of the Division of Child Hygiene of the Massachusetts Department of Public Health, Boston, Mass.

ARTHUR M. STOKES, M.D., a member of the staff of the Homer Folks Tuberculosis Hospital, Oneonta, N. Y., has been transferred by the Division of Tuberculosis, New York

* Fellow A.P.H.A.

† Member A.P.H.A.

State Department of Health, to become Superintendent of Mt. Morris Hospital at Mt. Morris.

JAMES WAILS, M.D., M.P.H.,* has been appointed Commissioner of Health for the City of Worcester, Mass. Prior to this appointment Dr. Wails was Director of the Nashoba Health Unit, Ayer, Mass.

HARRY C. WYER, M.D., who was formerly a Lt. Col. in the United States Army and Professor of Preventive Medicine and Military Tactics at the Boston University Medical School, has been appointed Health Officer of the South Metropolitan District of the Massachusetts Department of Health, Boston, Mass.

Southern States

THOMAS P. ANDREWS, M.D., has resigned as Health Officer of Brownsville, Tex.

JAMES A. MCCALLUM, M.D., C.P.H.,† Centerville, Md., has been appointed Health Officer of Queen Annes County, succeeding DR. WILLIAM R. WILLARD,† Hagerstown, Md.

WATSON S. RANKIN, M.D.,* Director of the Hospital and Orphan Sections of the Duke Endowment, Charlotte, N. C., has been elected Chairman of the Charlotte Board of Health.

LEWIS C. ROBBINS, M.D., C.P.H.,† P.A. Surgeon, U. S. Public Health Service Reserve, formerly Health Officer of Wichita Falls, Tex., was presented with the Distinguished Service Award of the United States Junior Chamber of Commerce on January 14. Dr. Robbins was cited for his successful conduct of a venereal disease control campaign that he instituted in Wichita Falls. He is now associated with the Public Health Department in San Antonio, Tex.

FRANCES C. ROTHERT, M.D.,* recently Regional Medical Consultant for the U. S. Children's Bureau in New Orleans, has resigned from the Chil-

dren's Bureau and has been appointed Acting Director of Maternal and Child Health in the Arkansas State Board of Health, Little Rock.

ELVIN L. SEDERLIN, M.D.,† Bismarck, N. D., has resigned as acting director of the Venereal Disease Control Division of the North Dakota State Health Department in order to accept a position as Assistant Health Director of Baltimore County, Md.

HARRY B. SMITH, M.D., formerly of Jacksonville, Fla., and now field consultant in the Division of Venereal Disease Control in the Maryland State Department of Health, has been appointed senior medical supervisor in the Bureau of Venereal Disease of the Baltimore City Department of Health, Md.

PROFESSOR CLAIR E. TURNER, DR.P.H., Sc.D.,* has been appointed Public Health Education Officer in the Health and Sanitation Division of the Office of the Coördinator of Inter-American Affairs, in which capacity he left for Brazil, Chile and Peru in March.

HERBERT T. WALWORTH, M.S.,* formerly Director of the Division of Industrial Hygiene, Montana Department of Public Health, Helena, Mont., has resigned to become Industrial Engineer of the Tennessee Department of Public Health, Nashville, Tenn.

CHARLES A. WYATT, M.D., Marshall, Tex., has been appointed Health Officer of Harrison County, Tex.

Western States

ALBERT D. BREWER, M.D., has resigned as City-County Health Officer of Bozeman and Gallatin County, Mont., to become staff physician at the Montana State Tuberculosis Sanitarium, Deer Lodge.

Epidemic Keratoconjunctivitis

Correlation of Epidemiologic Data and Results
of Serum Virus Neutralization Tests*

ROBERT F. KORNS, M.D., DR.P.H., F.A.P.H.A., MAJOR M.
SANDERS, M.C., AUS, AND R. C. ALEXANDER

*New York State Department of Health, Albany, N. Y.; Medical Corps, Army of
the United States; and College of Physicians and Surgeons, Columbia
University, New York, N. Y.*

DURING the course of the investigation of an extensive outbreak of epidemic keratoconjunctivitis in a large manufacturing plant in Schenectady, N. Y.,¹ opportunity was furnished to study further the significance of the virus neutralization test described by Sanders and his coworkers.² The purpose of this paper is to present the results of tests performed on sera from the Schenectady area, as well as previously unpublished data on a group from New York City. Although the number of persons studied was not large, it is felt that the findings are of sufficient significance to warrant presentation.

The outbreak in Schenectady was definitely established as one of epidemic keratoconjunctivitis upon clinical grounds. Most of the cases presented the typical signs and symptoms of the

disease noted by other investigators.³ Briefly, these included an initial hyperemia and follicular hyperplasia of the palpebral conjunctiva, without purulent discharge and with considerable edema of the periorbital tissues. Tearing and the sensation of foreign body in the eye were common. Later there was involvement of the bulbar conjunctiva, frequently with chemosis. Swollen and tender preauricular lymph nodes appeared commonly on the 3rd day of illness in practically all patients, and subepithelial corneal opacities developed in 87 per cent of the study sample. Approximately 4 per cent of the plant population developed clinical evidence of the disease during the course of the outbreak.

Attempts were made by Habel⁴ to isolate the virus of epidemic kerato-

* Presented at a Joint Session of the Epidemiology and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

NOTE: The laboratory phase of this study has been aided by grants from William R. Warner & Company, and from the John and Mary R. Markle Foundation.

conjunctivitis from the conjunctival scrapings of several acute cases in the Schenectady outbreak by means of tissue culture and intracerebral inoculation into mice. Although a number of the mice so treated developed a mild clinical illness on the 5th day after inoculation, a strain of the virus which could be maintained indefinitely was not obtained. In the study of this disease in New York City, Braley⁶ had the same experience in attempting to isolate the virus; namely, that the mice showed transient symptoms but recovered. In this instance, however, additional data of significance were obtained. Approximately 100 of his mice, showing in most instances clinical evidence of the disease but surviving primary inoculation with conjunctival scrapings from cases of epidemic keratoconjunctivitis, were challenged by graded doses of the mouse-adapted strain of virus previously isolated by Sanders. Whereas in an equal number of 100 control mice death occurred in all tested dilutions through 10^{-6} , the challenged mice were protected in dilutions of 10^{-6} , 10^{-5} , and 10^{-4} , and succumbed only to a 10^{-3} assault dose. Thus, while the injection of human conjunctival scraping did not produce a transmissible agent, protection was afforded against the previously demonstrated virus.

The technic employed in performing this neutralization test has been fully described elsewhere.² All that need be said here is that constant amounts of serum were mixed with tenfold dilutions of the virus, and the mixtures incubated for 1 hour at 37° C., and then placed in the icebox for 24 hours. Each serum virus mixture was injected intracerebrally into four Swiss mice. The titer of the serum as recorded in this paper represents the last dilution in which death occurred. Control mice uniformly died in all dilutions through 10^{-6} .

In order to avoid any possible personal bias in interpreting the results of these tests, sera submitted to the laboratory were identified by numbers only. Sera from 57 persons in the Schenectady area and from 46 in New York City, comprising a total of 118 specimens, were studied in this manner. Specimens were obtained from patients with epidemic keratoconjunctivitis early in the course of their illnesses, during convalescence, and after recovery, as well as from contacts known not to have had any eye complaint. Likewise, a group of controls were included consisting of persons known not to have suffered from the clinical disease and without history of contact with it. Some of these control individuals had ocular conditions other than epidemic keratoconjunctivitis, including various bacterial conjunctivides and corneal ulcer. Sera in these various categories were submitted at random and not all in one category at one time.

The results of the tests performed are tabulated in Table 1, and the percentage positive presented graphically in Chart I. It should be emphasized that little significance can be attached to the finding of neutralization in the 10^{-5} dilution, since the accuracy of the test does not allow such fine distinction. However, test sera with titers of 10^{-4} or less may be considered significant in the demonstration of neutralizing antibodies.

It is evident that sera obtained during the first week of illness from patients with typical acute epidemic keratoconjunctivitis, who subsequently developed corneal opacities, show no neutralization. The same is true of the groups of control individuals studied. On the other hand, the sera of all convalescent cases (6-10 weeks after onset) and 40 per cent of sera from cases taken 5 months after onset of illness, showed definite neutralization. Of particular significance was the marked

TABLE 1

*Extent of Neutralization to the Virus of Epidemic Keratoconjunctivitis
Shown by Selected Sera*

Titer of Serum	No. of Neutralizing Doses	Cases			Contacts		Control No Known E.K. or Contact	Total
		Early 1st Week	Convalescent 6-10 Weeks	Late 4-5 Months	Intimate (5 Months After Onset of Case)	Remote		
10 ⁻⁶	0	30	..	4	7	4	28	73
10 ⁻⁵	10	1	..	2	4	4	1	12
10 ⁻⁴	100	2	3	5
10 ⁻³	1,000	..	14	2	3	19
10 ⁻²	10,000	..	7	7
10 ⁻¹	100,000	..	2	2
Total		31	23	10	17	8	29	118

rise in antibody titer shown by 15 of the patients tested during the first week of illness and then 6 to 10 weeks later. The sera of all these persons were negative on the first test, but on second test showed at least 1,000 neutralizing doses. Two of this group developed titers of 100,000 neutralizing doses.

The healthy contacts studied have been divided into two groups; namely,

those with family or other intimate contact with the disease, including certain nurses and physicians handling large numbers of cases; and remote contacts including fellow plant workers or hospital personnel having no known direct contact with cases. The similarity of the findings in the group of late or recovered cases to those in the intimate contacts should be noted although the figures are too small to warrant definite

CHART 1

PERCENTAGE OF CERTAIN SELECTED SERA SHOWING
NEUTRALIZATION TO THE VIRUS OF EPIDEMIC KERATOCONJUNCTIVITIS
AS WELL AS THE TITER OF NEUTRALIZATION

conclusions. Both of these groups were examined about 5 months after onset of experience with the infection. Unfortunately, no sera from contacts were obtained during the period of early convalescence of the index case. One wonders whether such sera might not show higher levels of neutralizing antibodies.

Those intimate contacts with significant amounts of neutralizing antibodies in their sera deserve further comment. Of the 3 showing neutralization in the 10^{-4} dilution, or 100 neutralizing doses, one represents the plant ophthalmologist who handled the large majority of cases. The other 2 were intimate household associates of severe cases, who had nursed the patients during their acute illnesses. None of these persons gave a history of ever having conjunctivitis and careful examination of their eyes failed to show any evidence of epidemic keratoconjunctivitis or its residuals. Such a situation has a good precedent in equine encephalomyelitis, where laboratory workers handling the virus may develop high titers of neutralizing antibodies in their blood, without apparently having suffered from the disease.

The 3 persons exhibiting 1,000 neutralizing doses in their sera are of considerable interest since they are all from the same family of 4 resident members, in which the 4th member, the mother, suffered a typical case. These 3 individuals were studied in great detail, but no history of eye complaint nor evidence of epidemic keratoconjunctivitis on physical examination was uncovered. These three household contacts were employed at the plant where the outbreak occurred but the mother with the clinical disease rarely left home and never visited the plant. She was not aware of having had contact with any known case of epidemic keratoconjunctivitis. Two months after this initial test, or 7

months after the onset of the case, blood sera were again obtained from the members of this family. Significant neutralization, although in lower titer, was again found in serum from the patient and from 2 of the contacts, while serum from the third contact had become negative. (Results not included in table.) These findings suggest the possible existence of asymptomatic carriers of the virus.

SUMMARY AND CONCLUSIONS

Sera from cases of epidemic keratoconjunctivitis and their contacts, as well as from presumably normal control individuals and persons with other eye conditions, have been studied for the presence of neutralizing antibodies to the virus previously isolated from the conjunctival scrapings of cases of epidemic keratoconjunctivitis. It is felt that the data presented lend support to the conclusion that the virus isolated by Sanders is etiologically related to the disease. Although the number of healthy individuals studied was small, the evidence tends to confirm the possibility previously suggested¹ that a subclinical phase of the disease may exist.

The Uses of Penicillin

At the meeting of the American Philo-sophical Society in Philadelphia, Pa., April 20, Dr. Chester S. Keefer of Boston, who is in charge of civilian allocations of penicillin, summarized the utility of the new drug for a variety of conditions.

Confirming the great effectiveness of penicillin as recently reported in syphilis, Dr. Keefer stated that it is now the best remedy for controlling the gonococcus, meningococcus, and the staphylococcus and that it is effective for some of the streptococci and pneumococci.

He said that it is also useful for tetanus, gas gangrene, diphtheria, some of the pneumonias, and the large series of infections caused by the organisms already named.

According to Dr. Keefer, the drug is not useful in influenza, typhoid and paratyphoid fevers, in tularemia, bubonic plague, cholera, whooping cough, tuberculosis, nor any known virus diseases. He stated that, when organisms ordinarily susceptible to the drug become seated on the heart valves, penicillin loses most of its curative power.

Epidemic Keratoconjunctivitis— Detroit Experience*

JOSEPH G. MOLNER, M.D., F.A.P.H.A., AND E. L. COOPER, M.D.

*Deputy Commissioner and Medical Director, Detroit Department of Health; and
Consultant in Ophthalmology, Chrysler Motor Car Corporation, Detroit, Mich.*

REPORTS of epidemic keratoconjunctivitis have appeared in medical literature with increasing frequency since the early fall of 1941. Reference is made in these articles to the history of the disease and it is indicated that apparently the condition was recognized and originally reported by Fuchs.¹ Probably the first report of the occurrence of the malady in the United States was made by Hobson,² who reported 16 cases in a veterans' hospital in San Fernando, Calif. Increasing emphasis is given to the importance of the condition in this country in the reporting of 200 cases in San Francisco, Calif., by Hogan and Crawford.³ One hundred and one cases out of 125 studied were reported in one shipyard in the City of San Francisco and 92 of these patients, or 75 per cent, developed opacities of the cornea. The high incidence of the disease in industrial plants and the frequency with which opacities of the cornea develop show evidence of creating a major problem in war production plants. The epidemic nature of the disease and incidence of opacities result in the loss of many man hours of work. The opacities of the cornea peculiar to epidemic keratoconjunctivitis result in permanent and semi-permanent dis-

abling of employees engaged in work requiring acuteness of vision. These problems furnished the incentive for the Division of Preventive Medicine of the Surgeon General's office to call a conference of physicians and representatives of industry to discuss epidemic keratoconjunctivitis and the relationship of the disease to industry and the war effort.⁴ The conference stimulated a great deal of interest in the incidence of the condition and its handicapping characteristics both to the individual and to industry.

In the City of Detroit in the early winter of 1942-1943 no such cases had been reported, although an occasional acute conjunctivitis of unknown etiology had been seen by ophthalmologists. However, the need for planning the control of epidemic keratoconjunctivitis in a large industrial city like Detroit became evident to representatives of industry and the local Health Department. To plan the control of a possible outbreak, representatives of industry, the State Department of Health, and the Detroit Department of Health made arrangements with the New York State Department of Health and the Medical Director of one of the larger industrial plants which was experiencing a major outbreak of epidemic keratoconjunctivitis to visit this latter organization and to acquire first-hand information about the clinical characteristics of the disease, epidemi-

* Presented at a Joint Session of the Epidemiology and Laboratory Sections of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

ology, and recommended treatment procedures. Having had the benefits of the New York experience and the advice and guidance of the New York workers, the Detroit group laid its plans for the control of epidemic keratoconjunctivitis should the day arrive when cases of this disease would be reported in this area.

THE PLAN OF CONTROL

1. Epidemic keratoconjunctivitis was made a reportable disease with further provision that placarding of the case could be required at the discretion of the health officer.

2. Physicians, industrial nurses, first aid personnel of medical departments in industry, and industrialists were familiarized with the clinical characteristics of the disease, its mode of spread, and its handicapping features. To attain this, a series of conferences were held through the coöperation of the Wayne County Medical Society, the Detroit Ophthalmological Society, ophthalmologists, industrial physicians, and industrial nurses. Mimeographed information on the clinical characteristics of the disease, differential diagnosis, epidemiology, incidence of opacities, and the recommended treatment procedures were distributed for the use of these people.

Industry, in turn, circularized medical, nursing, first aid, and safety personnel with similar types of literature, and, in general, the administrative and executive staffs of industry were properly informed by their respective medical departments of the importance of the disease.

3. It became evident from recent reports in the literature and through conferences with the New York group that meticulous care and cleanliness were essential in the control of the spread of the disease, and that the "eye-to instruments (or fingers)-to-eye" route in eye clinics and physi-

cians' offices represented the most important means of spreading the disease. For these reasons through the coöperation of the Wayne County Medical Society and the Detroit Ophthalmological Society, a diagnostic and treatment clinic was established by the Detroit Department of Health to which industry and local physicians had the privilege of sending their patients. This clinic was set up for the proper handling of communicable eye conditions. Industrial medical personnel and practising physicians were invited to bring in their own cases or to attend the clinic at their convenience, and benefit from the experience of seeing the communicable disease technic as applied in the eye clinic by public health personnel.

4. An approach was made to industry to establish in the eye rooms and the eye clinics in the plants a similar closed communicable disease technic. The attendants in the eye clinic were required to wear gowns and rubber gloves and to scrub meticulously between cases. All contaminated eye-room equipment, such as glass rods, eye spuds, forceps, or any other instruments were required to be sterilized between individual cases. Under this plan it was necessary to use sterilized individual eye droppers for individual cases and the glassware and equipment had to be cleaned and sterilized daily. A small contaminated table and a clean table were set up in each of the eye clinics with specific instructions to attendants to place all contaminated material only on the contaminated table. The arm rests were removed from the eye chairs and each patient was instructed upon entering the room to hold his belongings, lay nothing down, and to touch nothing in the room. A detailed sterile-eye-room procedure was outlined and posted in each of the eye rooms in the industrial plants, and copies of these procedures were given to the attendants

in the first aid division of the plants.

Although the plan has been recommended and adopted in certain plants of establishing a separate eye clinic for the diagnosis of keratoconjunctivitis, the writers and their associates are firmly convinced that such a plan is contrary to good practice. It is quite probable that there are unrecognized carriers of epidemic keratoconjunctivitis. Furthermore, some clinical cases may at times be diagnosed as simple conjunctivitis and find their way to the eye room in which the usual technics are being utilized, with resulting transmission of the disease to others. It is the opinion of this group that a careful communicable disease technic followed in a single eye room in industrial plants is far more productive of good control results than the setting up of a different procedure for the handling of cases and suspected cases of keratoconjunctivitis.

5. Patients with the disease were excluded from work for the period of time that acute signs of the disease persisted, such as congestion and lacrimation. When, in the judgment of the physician, the patients were sufficiently recovered and were no longer considered infectious, the employees were given permits to return to work. The fullest coöperation of industry was experienced in this particular control procedure. Employees of the various industrial plants in Detroit and the Detroit area, upon having their condition diagnosed as keratoconjunctivitis or suspicious of keratoconjunctivitis, were immediately given lay-off notices, which were not terminated until the employees had received "return to work" permits from the local Health Department.

6. After diagnosis, patients were advised of the communicability of their condition, the seriousness of the disease, and what procedures were to be followed in the control of the spread of the

disease. Mimeographed information about sore eyes and precautions to be followed were given to every patient.

7. To give more complete information and assistance in the control of epidemic keratoconjunctivitis to industry, the Department of Health assigned communicable disease nurses the responsibility of visiting the industrial plants and assisting these organizations to establish good technic in their eye clinics. This service was offered to all industrial plants, both large and small, in Detroit; and in some instances to industrial plants outside the political boundaries of the city, but which employed residents of Detroit. When cases of epidemic keratoconjunctivitis were reported from a plant, these same nurses immediately solicited from the medical department an opportunity to assist in setting up proper technics in the eye clinic.

INCIDENCE

The first suspected case of epidemic keratoconjunctivitis was seen by the writers early in December, 1942. By retroactive investigations 16 cases of epidemic keratoconjunctivitis occurring between October 1 and December 19, 1942, were uncovered in a small industrial plant employing 120 persons. Of these cases 9 revealed corneal opacities and 1 of the 9 had extensive bilateral involvement with a 40 per cent reduction in visual acuity. It should be noted that the medical and first aid personnel of this organization were not aware of the fact that they were dealing with a communicable disease, and the control procedures referred to in this article were not established until the latter part of December; therefore only the last case reported from this organization developed after the inauguration of the precautionary measures in the eye clinic. No comparable attack rate was experienced in any other industrial plant in the Detroit area.

The diagnostic and treatment clinic at the Department of Health was established on December 19, 1942, and simultaneously the control procedures referred to above were in the process of promotion. During the following 6 months period 1,096 patients were seen in the clinic, of whom 247 were diagnosed as having keratoconjunctivitis. The largest concentrations of cases in industrial plants were 60 from a plant employing 90,000 persons, 29 from a plant employing 35,000 persons, and 20 from a plant employing 42,000 persons.

By comparing the experience subsequent to the establishment of the control procedures with the one outbreak prior to the efforts of the department, a difference is suggested in attack rates. Similarly, the attack rate of the disease in the Detroit experience was considerably lower than that reported by other writers. Although it cannot be said that the control procedures played a major part in the reduction of the incidence of the disease, it is probable that these practices did materially prevent the spread of keratoconjunctivitis in the Detroit experience. Certainly, meticulous care in the handling of all eye infections and eye injuries in industry as well as in the physician's office is necessary, and the educational value of these procedures to the medical personnel and patients is invaluable.

TREATMENT

Patients treated with the recommended standard methods of treatment showed very little evidence of benefit from these practices. Prescriptions of pontocain, adrenalin chloride, and a saturated solution of boric acid gave the greatest amount of symptomatic relief. Use of a 5 per cent solution of sulfathiazole sesquihydrate showed no evidence of benefiting the patients. After the disease had reached an advanced stage of development, cold boric

compresses and the pontocain, adrenalin chloride mixture resulted in material symptomatic relief. The covering of the eye with an eye pad is contraindicated in the opinion of the writers, although dark glasses resulted in some comfort to the patients. A small absorbent pad fixed under the affected eye was a practice acclaimed by most patients as very comforting. This small absorbent pad prevented the flow of tears down the cheeks of the patients and eliminated the annoyance and discomfort of wiping the tears and also spared mechanical irritation of the affected eye. Although apparently a very simple procedure, on the basis of the reactions of the patients so treated, this practice is highly recommended.

In the search for therapeutic agents for the treatment of active infections, biological substances obtained from organisms have been studied. As an outcome of such research two of the most promising bactericides, penicillin and tyrothricin, have been isolated. The work of Dubos⁵ on tyrothricin is suggestive of good results and the report of Rammelkamp⁶ lends further support to the usefulness of this agent.

The use of a 30 mg. per cent solution of tyrothricin* in the treatment of cases of epidemic keratoconjunctivitis was suggested. The writers and their associates began to use tyrothricin on cases of epidemic keratoconjunctivitis late in the period of the epidemic and the clinical impression after the use of the product in a small series of cases was that the duration of the disease appeared to be somewhat shortened. Approximately one-half of the patients claimed that they experienced some symptomatic relief. The most significant impression, however, was the marked reduction in the incidence of complications. Table 1 presents a comparison between cases which were

TABLE 1

Classification of 219 Patients According to the Duration of the Disease and Treatment

<i>Duration</i>	<i>Numbers</i>		<i>Percentages</i>	
	<i>Tyrothricin</i>	<i>Symptomatic</i>	<i>Tyrothricin</i>	<i>Symptomatic</i>
Less than 2 weeks	60	79	60	66
2 weeks or more	39	41	39	34
Total	99	120	100	100

TABLE 2

Classification of 219 Patients According to the Occurrence of Opacities and Treatment

<i>Sequellae</i>	<i>Numbers</i>		<i>Percentages</i>	
	<i>Tyrothricin</i>	<i>Symptomatic</i>	<i>Tyrothricin</i>	<i>Symptomatic</i>
Developed opacities	15	61	15	51
No opacities	84	59	84	49
Total	99	120	100	100

treated with tyrothricin and those which were treated by other methods. Two hundred and nineteen * cases are analyzed, of which 120 were treated by other methods and 99 were treated with tyrothricin. Table 1 does not reveal an appreciable difference in the duration of those cases treated with tyrothricin as compared to those treated by some other method.

In Table 2 the analysis of the same cases shows a marked difference in the incidence of opacities among those cases treated with tyrothricin as compared to those treated by other methods.

It seems apparent from Tables 1 and 2 that tyrothricin may be a valuable therapeutic agent for epidemic keratoconjunctivitis. However, the writers and their associates wish to acknowledge the fact that the experiment cannot be considered as well controlled.

In order to arrive at more reliable results, alternating cases of epidemic keratoconjunctivitis should be treated with tyrothricin and other therapeutic agents and certainly the series of cases should be larger than those herein presented. As noted heretofore, the use of tyrothricin was not started until

late in the course of studies and the number of cases reporting to the eye clinic were becoming fewer. There are certain variables which may be present and may tend to favor the results of using tyrothricin. Illustrative of such variables is that the 99 cases treated with tyrothricin were the last 99 cases referred in the eye clinic.

The use of tyrothricin in the treatment of keratoconjunctivitis is herein presented to call attention to this new therapeutic agent and its probable value, and to suggest that well controlled experiments in the use of this product in the treatment of epidemic keratoconjunctivitis are indicated. Such experiments will be carried on in the event of another outbreak in the City of Detroit.

SUMMARY AND CONCLUSIONS

Epidemic keratoconjunctivitis has been made a reportable disease in the State of Michigan. Making the disease reportable is one of the first and most important steps to be taken in the control of this condition.

The inauguration of communicable disease technic in the eye clinics of industrial plants is a very necessary part of adequate control. This does not mean that separate eye rooms

* Twenty-eight cases, in which records are incomplete, have been deleted from this group.

should be set up for the diagnosis of keratoconjunctivitis. In fact, the establishment of separate quarters and procedures for cases and suspected cases of keratoconjunctivitis is contraindicated in the opinion of the writers.

The use of tyrothricin in this experiment suggests that it may be a valuable therapeutic agent in the treatment of keratoconjunctivitis.

Von der Heide, M.D., and E. A. Sharp, M.D., for the preparation of the tyrothricin solutions and blood studies of treated cases.

Relocation of Physicians

The Procurement and Assignment Service of the War Manpower Commission announces the relocation of 2,955 physicians to new localities of practice from January, 1942, to February 20, 1944.

Five hundred and ten areas of the country have been reported as being critically short of medical personnel. "The needs have been met" in 281 communities, or 55 per cent of the critical areas. Relocations were effected in 135 of these communities and the needs of 146 were met by inducing re-

tired physicians to resume active practice, the "freezing" of medical personnel in civilian communities, and by other means.

The needs of 185 communities are reported as not yet met. In 166 areas no solution is apparent at present and only temporary or partial solutions have been effected in 16 areas. Mobile, Ala., Key West, Fla., Vallejo, Calif., and Velasco, Tex., are given as examples of communities in which medical facilities have been hard hit by the war and for which no solution has yet been found.

Current Progress in Sterilization of Air*

STUART MUDD, M.D., F.A.P.H.A.

*Professor of Bacteriology, University of Pennsylvania, School of Medicine,
Philadelphia, Pa.*

THE prevention and control of acute disease of the respiratory tract is the most serious problem and at the same time the most urgent challenge that today confronts medicine in general and industrial medicine in particular. Although diseases and injuries of occupational origin have long claimed the chief interest and attention of physicians in industry, it is now well established and generally recognized that in their frequency and importance non-occupational diseases far outweigh those conditions which arise from industry. The latter are chiefly responsible for stupendous losses in both time and money to employer and employee alike."

The sentences quoted opened an address by George Morris Piersol¹ at the Third Annual Congress on Industrial Health in January, 1941. Does examination of available data on industrial disability due to acute respiratory disease indicate that this challenge is being met in current practice? Quite the contrary. The frequency of sickness and non-industrial injuries causing disability for 8 consecutive calendar days or longer among a very large sample of industrial workers over the years 1933-1942 has been analyzed by the U. S. Public Health Service.² Sick-

ness absenteeism among males due to respiratory disease has shown a steadily mounting rate since 1938; the rate for 1942 was higher than in any previous year of the 10 year period. For females the rate has been steady since 1939 but at a high level. Moreover, respiratory sickness in male industrial workers in the first quarter of 1943³ was far higher than in the corresponding quarter of 1942; indeed the respiratory rate for the first quarter of 1943 has never been equalled or exceeded during the 10 year period, the first quarter rate of 1943 exceeding the 10 year mean rate by 52 per cent.

Whatever are the causes of this high and mounting rate of industrial disability due to respiratory disease, common sense cautions us not to seek the complete explanation in the conditions of work in industrial establishments alone. The packing of industrial and other workers in the ill-ventilated common carriers, trains, street cars, and busses, since rubber and gasoline shortages have been over-taxing already taxed transportation facilities, certainly provides one superlative opportunity for the spread of endemic and epidemic respiratory disease; crowded and confined places of amusement provide another.

In attempting to form even a rough estimate of the cost of this industrial disability, recourse may be had to smaller samples which have been sub-

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 13, 1943.

jected to more detailed analysis. Figures for a public utility for the period 1938-1941, inclusive, have been published⁴; these show that days lost from respiratory disease are more than a third of the total days lost from all causes of disability. Dr. Gafafer⁵ has kindly permitted use of a similar table for 1942. This gives the average number of absences lasting one calendar day or longer in a sample comprising about 2,500 male and 550 female employees in a public utility in 1942. The average number of days lost per person during 1942 due to respiratory disease was for males 3.1, for females 4.3. It is of course understood that the figures for one company cannot be taken as representative of conditions in American industries as a whole. These rates may be either too high or too low. To gain an idea of the approximate cost, if these rates were accurately representative, however, we may multiply these rates by the numbers of non-agricultural workers in the United States; these are approximately 26 million male and 14 million female workers.⁵ This yields an approximate total (with the reservations mentioned) of over 80 million man-days and over 60 million woman-days (or over 140 million person-days) lost to industry in the United States through respiratory disease in 1942. On the basis of 300 working days per year, this waste is approximately equivalent to the time of 470,000 persons working for a year.

The bureau of Labor Statistics publishes monthly data on straight-time hourly earnings for manufacturing industries in the United States as a whole.⁶ The author has computed an average daily earning by multiplying the straight-time hourly earnings (80.5 cents) by 8, the normal working day in American industry.* On this basis the loss in wages due to respiratory sickness amounts to roughly \$900,000, 000 per annum. This does not include

the expenses for medical care, overhead expenses arising out of idle machinery and interruption in production schedules, etc.

RELATIONSHIP BETWEEN RESPIRATORY DISEASE AND THE INFECTIOUSNESS OF AIR

Persons sneezing, coughing, or even speaking loudly expel into the air large numbers of minute droplets which may contain in a viable and infective state any pathogenic bacteria or viruses present in their oral secretions. The larger of these potentially infectious droplets have a flight range of about a meter; they are conspicuous, are easily recoverable on bacteriological plates, and their ability to transmit respiratory infection is obvious. When droplets or sputa have dried on solid surfaces their residues may become the source of infective dust.

The rôle of droplets was notably stressed by the German hygienist Flügge † in 1897,⁷ and the doctrines of "droplet-infection" and dust-infection, or transmission of respiratory infection by droplets and by infective dust dominated thinking in regard to respiratory disease for thirty years.

The greater part of the potentially infective material expelled by persons into the air, however, is not contained in droplets visible without special means, but in smaller droplets which evaporate almost instantaneously. The basic experimental demonstration was made by Wells⁸ in 1933-1934 that much of the enormous germ-load con-

* It is unfortunate that daily rates of pay are not available. Since the figure representing costs of time lost due to respiratory disease is at best only an approximate one the straight hourly earnings (excluding overtime earnings) are multiplied by 8 to secure a daily wage. It is recognized that this is somewhat arbitrary.

† Actually, however, Flügge himself appreciated the importance of invisible droplets accompanying the coarser visible droplets; these he recognized may persist in air for hours and reach distant parts of enclosed spaces.

veyed to the atmosphere by the evaporated residues ("droplet-nuclei") of these finer droplets, remains viable for hours or even days in the air of enclosed spaces and is wafted about like smoke to convey pathogenic bacteria or viruses to those who share the confined air. The atomizing of mouth and nose secretions into the air has lately been revealed with dramatic vividness by high-speed photography.⁹ The enormously important rôle of pathogens floating in confined air in the dissemination of respiratory disease has now been adequately documented by animal experiments, by observations in controlled human environments, and by epidemiological deductions; the evidence to 1941 has been conveniently assembled in the volume *Aerobiology*, published by the American Association for the Advancement of Science with the aid of the Committee on Aerobiology of the National Research Council.

Any attempt to appraise current progress in the sterilization of air must, however, take account of the historical background. Members of the medical profession who now occupy responsible positions in practice, in teaching and in administration have been thoroughly trained in the doctrine of "droplet-infection." Recognition of the greater importance of true air-borne infection has only come within the past ten years, and has deeply impressed only the relatively small number of those who have seriously examined evidence which is either very modern, or very old (of course important foundations of the germ theory of disease were laid by the studies of Pasteur, Tyndall, and others on microorganisms in the air). Lack of a more insistent demand on the part of the medical profession for practical solution of the problems of air-borne infection might seem incomprehensible if this background were lost sight of. Lacking adequate demand by many prominent members of the

medical profession for progress in securing pure air supplies, air conditioning, from the standpoint of health at least, has somewhat neglected the main point. The point is that, just as intestinal disease has in considerable measure been controlled by reducing the germ-load of water and milk, for the control of air-borne respiratory disease practical measures for reducing the germ-load of confined air must be instituted.

CONTINUOUS DISINFECTION OF AIR

Effective continuous disinfection of the air of enclosed spaces has already been shown to be practicable where conditions are favorable and where the problem is approached with adequate determination and technical facilities and skill. The practical means are physical (ultra-violet radiation, dust suppressive measures) and chemical (germicidal vapors). Doubtless physical and chemical means will each find appropriate place as mutually complementary measures in the fully matured art of providing non-infectious air in our future homes, transport vehicles, and places of work and recreation.

Ultra-violet Radiation—Application of ultra-violet radiation to disinfection of air has been systematically reviewed in the A.A.A.S. volume on *Aerobiology*. The physiological and the germicidal effects of ultra-violet radiation, and the characteristics and standardization of commercially available ultra-violet sources are presented in detail. Successful application of ultra-violet radiation to reduction of wound infections in the operating room are presented by Dr. Deryl Hart, the pioneer in this field, and by Drs. Kraissl and Wilson of Columbia. Cross-infections in hospital wards and in children's nurseries and schools are reviewed and analyzed, and success in reduction of these cross-infections by appropriate use of ultra-violet irradiation is recorded. More

detailed analyses of successful control of childhood contagions in schools have been published by Wells, Wells, and Wilder,¹⁰ and by Wells and Wells.¹¹

More recent records of germicidal action against bacteria and viruses by ultra-violet radiation in a children's hospital, with reduction in cross-infection, have been published by Robertson, Doyle, and Tisdale,¹² by Sommer and Stokes,¹³ and Henle, Sommer, and Stokes.¹⁴ The Council on Physical Therapy of the American Medical Association has found ultra-violet lamps acceptable as an adjuvant in the disinfection of air,¹⁵ and commercially available burners and fixtures of several types have been approved by the Council¹⁶ for use in the operating room, hospital nursery, and hospital ward.

The statement of the Council on Physical Therapy on acceptance of ultra-violet lamps for disinfecting purposes contains carefully considered appraisal of the present status of the practical art. Pertinent statements are quoted below:

"At the present juncture the design and installation of ultra-violet lamps in their fixtures for disinfecting purposes is empirical and the adequacy of disinfection by any given installation of lamps must be judged by clinical experience. For example, clinical evidence has been submitted to the Council showing that, in a scarlet fever ward (size about 60 by 27 by 11 feet) containing sixteen cubicles, four lamp units, each one emitting a radiant flux of 30 microwatts per square centimeter at 1 meter, were found inadequate; but eight lamp units in the ward, each unit protecting two cubicles, and a ninth unit at the entrance, prevented cross-infection. This is a rather high intensity (requiring twenty minutes calculated time to produce a minimum perceptible erythema) incident on a person of average height, standing directly under a lamp fixture suspended from a ceiling of average height. A greater number of lamps, each one of lower ultra-violet intensity (say 20 microwatts per square centimeter at 1 meter) and lower power input, more evenly distributed throughout the room should be safer and equally efficient in disinfecting the air. This is a matter of engineering design, beyond the scope of the Council's purview.

"Since the ultra-violet emission from the low vapor pressure mercury discharge tube is practically homogeneous radiation of wavelength $2,537\text{\AA}$, such a lamp can be readily calibrated in absolute value and used as a standard. The intensity at 1 meter may be only one-fifth of the Council's unit, or 20 microwatts per square centimeter, for safety to the occupants. This will require a minimum exposure of two hundred and fifty to five hundred seconds for adequate disinfection, which will depend on the rate of circulation and average distance of the air in front of the lamp. Evidence has been submitted to the Council showing that cross-infection in a contagious ward may be prevented by using a sufficient number of lamp units, each unit having an intensity of 30 microwatts per square centimeter at a distance of 1 meter from the burner. This will require an exposure of one hundred and sixty-seven to three hundred and thirty-four seconds for adequate disinfection, which implies a slow movement of the air in front of the lamp installation.

"The use of ultra-violet radiation for disinfecting air in industrial plants, barracks, school rooms, assembly halls, refrigerators and so on also appears to be outside the Council's purview. In fact, at this juncture the whole question of the use of ultra-violet radiation for disinfecting purposes is too complex and too little understood for the Council to do more than attempt to keep the medical profession informed regarding particular ultra-violet lamps that are acceptable for use in this method of disinfecting air in hospitals, nurseries and operating rooms (relatively free from dust) as practiced by present day empirical methods."

It must be emphasized that the Council's acceptance statement does not prejudice the applicability and the usefulness of ultra-violet radiation to the problem of disinfecting the air of industrial plants, offices, assembly halls, railroad cars, etc. It emphasizes, however, that the specifications of engineering design and other features determining the adequacy and safety of the practical art must be further developed and applied before evaluation will become possible.

Another paragraph of the Council's statement discusses responsibility for design of installations.

"It is to be noted that a lamp used for disinfecting purposes is a single unit in an installation, and that compliance of the ultra-violet output of a single lamp unit with the Council's requirements does not insure adequate radiant disinfection or the safety of the occupants of the room in which an installation of such lamps is in actual use. Obviously the manufacturer and distributor of such lamps must assume some responsibility for the adequacy of the lamp installation for purposes of radiant disinfection of the air and for the adequacy of the protection from injury of the occupants of the space irradiated. Concerning these questions the Council cannot undertake supervision or assume responsibility for the satisfactory performance of any particular installation."

The Senior Biophysicist of the Division of Industrial Hygiene, National Institute of Health (who also is Associate Referee for the A.P.H.A. on Disinfection of Air by Ultra-Violet Irradiation), has critically reviewed applications, precautions, and limitations of the use of ultra-violet irradiation to disinfection of air.¹⁷ The statement of the Council on Physical Therapy is quoted with approval¹⁷: "Obviously the manufacturer and distributor of such lamps must assume some responsibility for the adequacy of the lamp installation for purposes of radiant disinfection of the air, and for the adequacy of the protection from injury of the occupants of the space irradiated."

Acceptance by the engineering groups in whose province air hygiene may be considered as properly falling, of a measure of responsibility for elaborating specifications for proper design and servicing of installations would be an important step toward development of a practical art of air hygiene.

The efficacy of ultra-violet irradiation in killing air-borne bacteria and viruses under conditions in which the air is relatively free from dust and lint has been confirmed in Great Britain by Andrewes and others¹⁸ and by Edward, Lush, and Bourdillon.¹⁹ The difficulty of disinfecting dust-laden air by this

means has also been emphasized. Andrewes, *et al.* suggest the combination of air filtration and ultra-violet irradiation in recirculation systems and for certain special purposes.

Germicidal Vapors—The spraying of germicides into the air was of course a part of the technic of antiseptic surgery. Modern interest in germicidal mists was stimulated by the demonstration by Douglas, Hill, and Smith,²⁰ Trillat,²¹ Masterman²² that certain bactericidal substances, e.g., NaOCl and a number of phenolic compounds, when dispersed in the air as fine mists or aerosols exerted a highly lethal effect on air-borne bacteria. Twort, Baker, Finn, and Powell²³ found that hexyl-resorcinol dissolved in propylene glycol made a highly effective and satisfactory germicidal aerosol.

An inclusive and practical discussion of the problems of air-borne infection and means for its amelioration in war-time Britain has been presented by Andrewes and others.¹⁸ Concerning germicidal mists and vapors they conclude:

"Hexyl-resorcinol in propylene glycol has proved perhaps the most effective under laboratory conditions, but unfortunately neither the antiseptic nor its solvent is at present readily enough available* in large amounts to warrant its introduction except for special purposes."

Considerations of economy and practicability as well as of efficacy have served to focus attention in Britain on the germicidal value of hypochlorites and hypochlorous acid. Actually the use of hypochlorites for purification of air was first tried in England as early as the influenza pandemic in 1918. Masterman²⁴ reviews in detail the early history and various controversial aspects of the use of hypochlorites for air purification. He describes an atomizing de-

* Hexyl-resorcinol is at present available in limited amounts and the glycols are available in large amounts in the United States.

vice (Dynalysor) as already in successful operation. "For many months the Dynalysor has been successfully employed for hypochlorite spraying in hospitals, offices, and other inhabited rooms, and air purification by hypochlorites is not a scheme 'with definite possibilities' but a successful *fait accompli*." Masterman concludes that HOCl gas is the active germicide in hypochlorite spraying.

Bourdillon, Lidwell, and Lovelock²⁵ have reported success with hypochlorite atomized by a hand spray in disinfecting air contaminated by sneezing. They note certain unfavorable conditions, "such as low relative humidity or high content of organic matter in the air, which may hinder the action of hypochlorite sprays."

Edward and Lidwell²⁶ report favorable tests on sterilization of air-borne influenza virus with hypochlorous acid gas.

"A concentration of 1 vol. of gas in 2 million vol. of air is probably effective in destroying 99 per cent or more of virus particles when the proportion of these in the air is small. Preliminary experiments on mice and cats are recorded which failed to reveal any toxic effects produced by inhaling the gas in relatively high concentrations or for prolonged periods. Acute irritation of mucous membranes only was found. This did not appear to lead to any increased susceptibility of mice to subsequent infection with influenza."

Exploration of the possibilities of continuous disinfection of air by chemical substances has made and is making rapid progress in America through the work of O. H. Robertson and his associates. They determined that certain of the glycols alone, notably propylene glycol²⁷ and triethylene glycol,²⁸ provided promising means for continuous disinfection of air. They demonstrated that the germicidal action depended, not, as earlier supposed, upon collision of fluid droplets with air-borne bacteria, but upon condensation of hygroscopic

glycol molecules upon air-borne droplets containing bacteria. One gram of propylene glycol dispersed as vapor in 5 or 10 million ml. of air and 1 gram of triethylene glycol vapor in several hundred million ml. of air was found to kill pathogenic respiratory bacteria and the virus of influenza in air in seconds or minutes. Rat and monkey colonies kept constantly in atmospheres saturated with vapors of propylene glycol for periods up to 18 months, and triethylene glycol up to a year suffered no ill effects detectable by observation or microscopic examination.²⁹

"The germicidal activity of glycol vapors is markedly influenced by certain environmental factors, the most important of which is atmospheric humidity.²⁹ A dry atmosphere is unfavorable. Likewise desiccated bacterial particles are not as susceptible to the vapor action as are moist ones. It has been found that the glycols are most effective at relative humidities between 40 and 60 per cent."

Subsequent work by Bigg, Jennings, and Fried^{30, 38} places the relative humidity for maximal germicidal action of glycol vapors at from 30 to 50 per cent. These papers^{30, 38} indicate also the types of apparatus that are being developed for disinfection of the air of large enclosed places by glycol vapors.

Careful investigation of the possibility of fire hazard resulting from the dispersal of glycol vapors into the atmosphere of enclosed spaces has also been made by Bigg, Jennings, and Fried.³¹ These authors conclude:

"In the vapor-phase concentration required for air sterilization, propylene and triethylene glycol offer absolutely no fire or explosive hazard. The addition of water to these substances greatly reduces the possible fire hazard produced by their presence in storage or vaporizing devices."

Clinical application of glycol vapors during the winters of 1941-1942 and 1942-1943 are recorded by Harris and Stokes^{32, 33} working at the Children's Seashore House in Atlantic City. This

convalescent home has a relatively stable population and the children in the wards are confined to their beds and thus subject to a minimum of contact or direct-droplet infection. Experimental and control wards were carefully matched; indeed in the second study³³ control and glycol-vapor wards were alternated for 3 week periods throughout the respiratory season. Ill effects were not encountered. The germ-load of the air was shown to be greatly reduced by the glycol vapors as judged by direct plate counts. In the preliminary study 2 respiratory infections occurred in the vapor-containing ward as compared with 16 in the analogous control ward. In the second and larger study 5 respiratory infections occurred in the vapor-containing wards as compared with 100 in the similar control wards without glycol vapor.

In his report as Associate Referee on Disinfection of Air by Germicidal Vapors and Mists,³⁴ Professor O. H. Robertson writes:

"Practical application of the use of glycol vapors for the purpose of controlling air-borne infection has had to await the construction of suitable apparatus for the dispersion of glycol vapors into large enclosed spaces and the development of an instrument to control automatically the concentration of glycol vapor in the air. Rapid progress is being made in the solution of both these problems."

Discussion of dust in industry would be outside the scope of this review. Consideration of the air as a vehicle of infection would be very incomplete, however, without reference to the importance of dust, both as a carrier of pathogenic bacteria and viruses and as a shield of air-borne pathogens against the means used for disinfection of air, such as ultra-violet radiation and germicidal vapors. British investigators³⁵ in particular, working under wartime conditions, have found dust a very serious obstacle to application of meas-

ures for disinfection of air. They have introduced practical methods for reducing dust from floors, textiles, and bed clothes by treatment with light paraffin oils.^{18, 35}

Experiments on the reduction of the infectivity of dust by floor irradiation with ultra-violet have been instituted by Hollaender, du Buy, Ingraham, and Wheeler.³⁶ As a result of these experiments they suggest that "floor irradiation be combined with ceiling irradiation in practical tests in barracks or hospital wards to determine the effect of any ultra-violet irradiation in lowering morbidity rates or preventing cross-infection." They caution that "if such experiments be attempted it must be borne in mind that certain types of flooring may prove to be capable of reflecting sufficient amounts of ultra-violet to cause harmful effects."

As this review goes to press (April, 1944) the author is informed by Dr. Edward Bigg^{37, 38} that practical apparatus has been constructed and utilized for introduction into the air of properly humidified glycol vapors. Boiling glycol-water solutions are maintained automatically at any desired relative concentration. "The vapors emitted from such boiling solutions are of constant composition and are bactericidal. . . . A predetermined rate of delivery and concentration of water and glycol vapor may be accurately produced by varying the heat input and the temperature of the boiling mixture."³⁷

SUMMARY

Respiratory disease is responsible for more than a third of the total number of person-days lost to American industry by disability. The air of enclosed spaces is at present the principal vehicle for the dissemination of respiratory disease. The rationale of rendering air safe for human occupancy has been laid down in the laboratory and in suitable controlled human environments.

The means are ultra-violet irradiation, dust-suppressive measures, and the use of germicidal vapors of hypochlorous acid and of propylene and triethylene glycol. Elaboration of the practical art of providing safe air supplies is, however, not to be accomplished cheaply or through the efforts of a few people. A specialty or specialties in sanitary engineering will have to develop around air sanitation, as has occurred around water and milk sanitation. Physicians, air conditioning specialists, heating, ventilating, and illuminating engineers, the manufacturers of necessary equipment, agencies regulating public health practice; and the industries which will benefit by reduction of industrial disability through respiratory disease ultimately will all have to contribute effort and money to solving the manifold aspects of the problem. How much is it worth to reduce an annual industrial waste equivalent to the output for a year of approximately 470,000 persons?

Baruch Grant for Physical Medicine

Bernard M. Baruch, Washington, announced in April a gift of \$1,100,000 for teaching and research in physical medicine. The inauguration of the program was through the Baruch Committee on Physical Medicine, of which Ray Lyman Wilbur, M.D., Chancellor of Stanford University, is Chairman.

The committee has announced a grant to Columbia University College of Physicians and Surgeons, New York, of \$400,000 for the establishment of a key center of research and teaching of physical medicine, with special reference to its application to returning veterans. The sum is to be expended over a 10 year period to give immediate assistance in maintaining an adequate supply of medical specialists to handle the

problems of war and post-war physical rehabilitation. Similar grants of \$250,000 each were made to New York University College of Medicine, and the Medical College of Virginia, Richmond, from which the late Dr. Simon Baruch, father of Mr. Baruch, graduated in 1862.

Selected medical schools are to receive another \$100,000 to develop an immediate program for the physical rehabilitation of war casualties and those injured in industry and \$100,000 is set aside for the establishment of Fellowships or Residencies in this field.

The offices of the committee have been established under the direction of Frank H. Krusen, M.D., at 597 Madison Avenue, New York, N. Y.

Nutritive Value of Canned and Dehydrated Meat and Meat Products*

E. E. RICE, PH.D., AND H. E. ROBINSON

Nutrition Division, Research Laboratories, Swift & Company, Chicago, Ill.

DURING the last few years a considerable fund of information regarding the nutritive quality of meat has accumulated in the scientific literature. Most of these data refer to raw products. Since the effect of cooking or processing upon the various nutrients has been relatively little known until recently, calculations of the dietary contributions of meat have been difficult. Within the last two years, many studies of the effects of temperatures similar to those used in household cooking have been completed and we are now able to assess more accurately the contribution by meat to the diet.

However, the nutritive value of commercially processed meats has not been studied adequately. With these products another complicating factor, that of storage, may be as important as the processing operation itself with respect to the retention of certain of the vitamins. The work reported here has been carried out in an effort to provide information concerning changes which may occur during either processing or storage. Attention has been directed mainly toward canned and dehydrated meats. Other studies dealing particularly with the changes in the quality of the protein during the preparation of these types of products

have already been reported by Poling, Schultz, and Robinson.¹

Using rats as experimental subjects, these investigators found no appreciable differences between the growth promoting properties of canned or dehydrated meats and the corresponding raw products when the various samples were used as sole sources of protein at adequate levels in the diets. Two series of experiments were conducted. One was designed to detect even slight variations in quality; and the other to determine whether differences which might be detectable were of practical significance. For the first series the proteins were supplied at a 9 per cent level, thus making protein the factor limiting growth. Under such conditions the animals were especially sensitive to differences in protein quality. In the more practical experiment, proteins were supplied at an 18 per cent level. Table 1 summarizes the data as previously reported.

Referring to Table 1, it is evident that there is a slight difference in the food efficiency in favor of the raw meat as compared to canned. While the difference only borders on statistical significance, it indicates that there may be a reduction in protein quality in the canned products. From Experiment 2, it appears that dehydrated beef is equal in protein quality to canned cured pork, but slightly inferior to dehydrated pork. That heating reduces the nutritive value of proteins

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

‡ 10 weeks' duration (ad libitum feeding)

** 8 weeks' duration (paired feeding)

has been inferred by other investigators² who implied that the reduction in quality was great enough to be significant for human consideration. The data in Table 1 refutes this assumption, since animals receiving 18 per cent protein diets showed the same gain per gram of food regardless of whether the protein was supplied as raw, cooked, canned, or dehydrated meat. As this level of protein corresponds to that customary in human diets, it is evident that the nutritive qualities of the proteins have not been impaired for dietary considerations.

As reported hereafter, the effects of processing on the vitamin content of meats indicates that there is little if any greater loss of vitamins during canning or dehydration than during home cooking of similar cuts of meat. The losses also appear to be similar to those involved in cooking or canning of most cereals or vegetables. This evidence has been obtained by assaying representative portions of meat at various stages during the processing operations.

EXPERIMENTAL

Analytical Methods—All samples were prepared for analysis by homogenizing with a known quantity of water in a Waring Blendor. Aliquots of the suspensions were then weighed into volumetric flasks and assayed for thiamin by the Conner and Straub³ modification of the thiochrome procedure, and for riboflavin, niacin, and pantothenic acid by methods similar to those of Cheldelin, Eppright, Snell, and Guirard.⁴

Vitamin Retentions During Dehydration—The preparation of dehydrated meats and methods of sampling have been previously described.⁵ For stability studies 1 lb. cans filled with a well mixed commercially dehydrated pork were closed under vacuum in the regular canning line and stored at various temperatures.

That dehydrated pork or beef retains most of the vitamin content of the original meat is shown in Table 2. For comparison the percentage retentions of the various vitamins during cooking

of pork by methods used for meat of similar quality is included in this table. This subject has been discussed elsewhere in greater detail.⁵ The excellent retention of the vitamins in these products is due in part to the utilization of cooking juices.

Vitamin Retentions During Canning—Raw pork trimmings, ground and well mixed, were sampled before the addition of curing mixture amounting to approximately 5 per cent by weight. After curing, the meat was divided into two portions, one portion being packed into 12 oz. cans and the other into 6 lb. cans. Samples were taken and the remainders of the two lots of cans were processed according to the regular commercial schedules. Six lb. cans were held at 235° F. for 3½ hours in order to assure a center temper-

ature of 225° F. The 12 oz. cans required a few minutes more than an hour at 232° F. The entire contents of representative cans were ground and mixed prior to sampling, thus assuring even distribution of the small amounts of broth. Twelve oz. cans of the finished products were stored for stability studies. The analytical data obtained on the raw, raw cured, and canned samples are presented in Table 3. In the 6 lb. cans, 43 per cent of the thiamin was retained as compared to 67 per cent for the 12 oz. pack. Except for thiamin there appears to be no difference in the vitamin retention in content of the two sizes of containers. Unfortunately, inhibiting substances in the raw meat or stimulating substances in the cooked products interfered with the microbiological assays at the time the experiment was

TABLE 3

*Vitamin Retention in Cured Pork During Canning**Vitamin Content in Mg. per Gram*

<i>Type of Product</i>	<i>Thiamin</i>	<i>Niacin</i>	<i>Riboflavin</i>	<i>Pantothenic Acid</i>
Cured Luncheon Meat				
Raw	7.5	37.0	2.3	4.1

Canned (12 oz.)	5.4	35.4	1.5	2.5
Retention	68%	94%	90%	76%

conducted, so that the recoveries of niacin, riboflavin, and pantothenic acid were exaggerated. However, the similar values obtained for different sizes of cans indicate that except for thiamin the more severe processing schedule necessary for the larger cans did not affect the vitamin potencies. After improvement of the microbiological methods, a number of experiments with 12 oz. cans were performed to eliminate the effect of interfering substances. Results from one such experiment have been listed in Table 3. Cessation of the production of 6 lb. packs has prevented repetition of the earlier work.

These data are in close agreement with those of Reedman and Buckley,⁷ who very recently reported thiamin retention in 6 lb. packs of Canadian pork luncheon meat to be 47 per cent of the amount in the raw meat. The findings are markedly different from those of Stanley⁸ who claims the thiamin retention of commercially canned or home canned pork to be only 20 per cent. Unfortunately, her data are not presented, so the experimental conditions cannot be compared with those now in use. This great loss appears to be entirely out of line with the thiamin retentions found for other cooking and canning operations and

must represent samples that have been prepared by long heating at high temperatures. Although commercial processing methods differ greatly from those used in household cookery, the retention of the vitamins by both methods is practically the same if the vitamin content of the cooking juices is included with that of the cooked meats.

Vitamin Retentions During Storage—

In order to determine the effect of storage upon the vitamin content of these products, replicate samples of canned cured pork (12 oz. sample) and of dehydrated beef and dehydrated pork were stored at constant temperatures of -20° , 38° , 80° , 99° , 120° , and 145° F. (-29° , 3° , 27° , 37° , 49° , 63° C.). All samples were vacuum packed, this being the usual commercial procedure. At intervals samples were removed for assay. In canned pork, there was excellent retention of the vitamins at temperatures to which this type of product would ordinarily be exposed (Table 4). Even thiamin, the most thermolabile of the B-factors determined, is retained to the extent of 52 per cent for a period of about 10 months at 80° F. At 38° there is only 7 per cent loss of this vitamin. At higher temperatures the loss is

TABLE 4

*Retention of Vitamins in Canned Pork During Storage**

Vitamin	Storage Period Days	Storage Temperature in °F.					
		-20°	38°	80°	99°	120°	145°
Thiamin	28	4.9	4.7	4.6	4.1	2.9	0.8

* Potencies of the samples are listed in micrograms per gram

naturally much more rapid. This fact should be kept in mind during the handling of canned meats. The beneficial effects of cool storage temperatures hold here as with other foods.

Even at 99° F., there is very little if any loss of niacin, riboflavin, or pantothenic acid. Under more severe storage conditions, 120–145° F. the latter two are destroyed to some extent. Since such high temperatures are rarely encountered by products for domestic consumption, the niacin, riboflavin, and pantothenic acid contents of canned meats may be expected to remain constant for long periods of time.

Dehydrated pork, like the canned product, retained niacin, riboflavin, and pantothenic acid well at temperatures up to 99° F. (Table 4). Above this there were losses of riboflavin and pantothenic acid. Even 145° F. storage did not reduce the amount of niacin in the samples. Thiamin appears to be less stable than in the canned pork, decreasing in quantity rather rapidly, even at 80° F.

Although storage of dehydrated beef has been studied much less extensively, the results indicated vitamin losses no greater than those for pork. Retentions of niacin, riboflavin, and pantothenic acid were 100 per cent after 219 days storage at 99° F. The initial low thiamin potency of dehydrated beef made it difficult to obtain accurate results with this vitamin, but those obtained indicate that the retention of thiamin was no better than that of dehydrated pork.

DISCUSSION

Dehydration or canning of meat does not greatly reduce its nutritive quality, the greatest of the changes which do take place occur in the thiamin and pantothenic acid potencies. Likewise, storage of processed meats at moderate temperatures does not affect their food value except for loss of thiamin. Under

ordinary storage conditions the other vitamins appear to be stable for indefinite periods. At temperatures of 120° F. and above, there is a gradual slow decrease in the riboflavin and pantothenic acid contents. When such temperatures are encountered during the transportation and storage of foods, as in tropical regions, these losses and those of thiamin must be considered by those concerned with dietary problems.

Since dehydrated or canned meats are already cooked, they may be consumed as purchased, merely warmed, or mildly cooked in combination with other foodstuffs. Losses in preparation for consumption, therefore, are slight. Meat loaf composed largely of reconstituted dehydrated pork retains 80 per cent of the thiamin of the raw meat loaf mixture. Decreases in the quantities of the other vitamins are negligible, the values for the raw and cooked loaves checking within the limits of accuracy of the methods.

In so far as can be determined from the limited data available, the effects of processing upon other foods are similar to those upon meat. Baking of bread involves losses of 20–21 per cent of the thiamin⁹ but does not decrease the amounts of riboflavin.^{10–11} Vegetables lose from 10 to 40 per cent of their thiamin during dehydration or canning¹² and an average of 35 per cent in cooking.¹³ Russell, Taylor, and Beuk¹⁴ show that in cooking various types of vegetables, niacin is retained to the extent of 80 to 90 per cent if the cooking liquors are included with the solid portions. Storage of dehydrated vegetables apparently does not greatly decrease the thiamin content,¹² but Farrell and Feller¹⁵ report storage of canned green beans for a year at 38° F. to result in a 28 per cent loss of this vitamin. Destruction of thiamin due to processing of evaporated milk ranges from 23 to 35 per cent. Storage increases this loss by

another 50 per cent in one year.¹⁶

Cereals and legumes ordinarily show little loss of any of the vitamins except during baking or long cooking unless the cooking water is discarded. Except for these, the vitamin losses for meats are typical of all classes of foodstuffs.

SUMMARY

1. Protein quality is not significantly reduced during dehydration or canning unless diets very low in proteins are considered.

2. Vitamin retention of pork and beef undergoing dehydration or canning is similar to that for household cooking of similar meats, being: Thiamin, 60-70 per cent; riboflavin, 90-100 per cent; niacin, 90-100 per cent; and pantothenic acid, 70-80 per cent.

3. Cured pork undergoing commercial canning (12 oz. can) retains 67 per cent of its thiamin, 90 per cent of its riboflavin, 94 per cent of its niacin, and 76 per cent of its pantothenic acid. Thiamin retention in 6 lb. cans is lower, being 40-50 per cent.

4. During storage of either canned pork, dehydrated pork, or dehydrated beef at temperatures up to 99° F. there is little or no loss of niacin, riboflavin, or pantothenic acid over a period of 219 days. Above 120° F. there are slow losses of riboflavin, and pantothenic acid. Thiamin decreases more rapidly, showing some loss at 80° F. After 293 days' storage the thiamin retention in canned pork is 52 per cent. In dehydrated pork the retention is poorer, being 29 per cent after 219 days at 80° F. At higher temperatures there is almost complete destruction of thiamin in both products.

Nutritive Values of Canned Fruits and Vegetables*

J. F. FEASTER, PH.D.

Research Department, American Can Co., Maywood, Ill.

ANY consideration of the effect of food preservation methods on foods might well be prefaced by a description of the characteristics of freshly harvested foodstuffs. An examination of tabulations of proximate compositions of foods¹ suggests that in general fruits and vegetables are not particularly important dietary sources of carbohydrates, proteins, or fats. Exceptions to this generalization may be found in the case of carbohydrates in fruits packaged in heavy syrup, proteins from the legume type vegetables, or even the oils in ripe olives. Aside from their esthetic properties, the high position accorded fruits and vegetables is thus based largely on their contributions of other nutrients.

The wide variety of fruits and succulent vegetables used for food precludes, however, any detailed review of the dietary properties of individual products. In view of the variations in contents of nutrients from sample to sample a detailed consideration of the mineral and vitamin values of specific foods would be of questionable importance. By way of illustration, ascorbic acid values ranging from 9.8 to 55.8 mg. per 100 gm. for tomatoes and 14.0 to 82.5 mg. per 100 gm. for oranges have been reported.² Vitamin A values ranging from 1,700 to 36,000

International Units per 100 gm. of carrots and thiamin values of 100 to 840 μ g. per 100 gm. of peas are also reported. Variations of these orders in mineral contents from sample to sample of specific vegetables have also been observed.³ Hence, the more useful practice of grouping fruits and vegetables according to similarities in nutritive values might be considered, such as:

1. Tomatoes and citrus fruits
2. Leafy green and yellow vegetables
3. Other fruits and vegetables

This classification provides a practical and convenient basis for discussion of dietary values of the canned as well as the fresh varieties.

The recommendation⁴ that in practical dietary management two or more servings of products included under "other fruits and vegetables" be eaten every day, is predicated on the general vitamin and mineral values of such foodstuffs, especially in the amounts customarily consumed. The specific recommendation of at least one serving of, "tomatoes and citrus fruits" per day is based on the relatively high ascorbic acid contents of these materials. The exceptional values of, "leafy green and yellow vegetables" as sources of provitamins A make the inclusion of at least one serving of them per day also highly desirable.

Since variations from sample to sample in the composition of raw stock

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

are reflected directly in the canned products, the nutritive values of canned fruits and vegetables may best be discussed in terms of properties of the vitamins and minerals, and the possible effects of cannery operations on these constituents in foods.

SOLUBILITIES AND STABILITIES OF NUTRIENTS

The known stabilities of sugars, starches, fats, proteins, crude fiber, and organic acids in fruits and vegetables to moist heat indicate that the chief changes with respect to these nutrients likely to accompany canning are associated with manipulations prior to sealing the product in the can. Although there is some uncertainty regarding the effects of moist heat on the biological values of protein, available data do not suggest that the thermal processes employed in canning are likely to affect materially the biological values of vegetable proteins. Since there is no question as to the heat stability of minerals, the influence of canning on these nutrients is confined to mechanical separations, leaching effects, or possibly changes in availability.

Of the fat soluble vitamins, the provitamins A are the least stable in vegetable materials. Other than a susceptibility to oxidation after maceration of vegetables under conditions which do not inhibit enzyme action, the provitamins A in vegetable products appear to be well retained. The water insoluble nature of the fat soluble vitamins minimizes sacrifices of these factors through leaching during washing operations. Mechanical removal of certain tissues during preparatory operations may, however, influence the vitamin A activity of vegetables as finally eaten.

Of the nutrients in fruits and vegetables, the water soluble vitamins appear to be most susceptible to sacrifice during cannery operations and their

solubilities present one avenue by which they may be removed in canning or in ordinary food preparatory operations. The relative heat labile nature of thiamin and the ease of oxidation of ascorbic acid suggest the need for exercise of proper precautions in food preparation or preservation methods to permit maximum retention of these factors.

BASIC STEPS IN CANNING

In the various methods employed for preserving fruits and vegetables, the primary objective is the conversion of perishable, seasonable foodstuffs into staples which can be stored, distributed, and later consumed as desired. Most canning operations, with the exception of filling, permanently sealing the container, and subjecting the product to a heat treatment adequate for commercial sterilization, have their counterparts in ordinary methods of food preparation, and, just as methods employed in the preparation of raw foods for serving may vary from product to product, canning methods may vary from product to product and even cannery to cannery except for the more highly standardized products.

CANNING ACID PRODUCTS—CHIEFLY FRUITS

In broad detail, three general patterns are followed in the preparation and commercial canning of fruits and vegetables. Under one may be discussed the canning of fruits (acid product, with pH values below 4.5) as large discrete particles. In this instance, the raw foodstuff upon receipt at the cannery is subjected to thorough cleaning, including washing, followed by removal of undesirable or inedible materials such as skins, pits, seeds, etc. Depending upon the style of pack, fruits may be subjected to further operations to produce pieces of the desired sizes and shapes. As is gener-

ally known, the prepared fruit in proper amounts along with a suitable packing liquid medium—either a sugar syrup or a fruit juice—is packed into cans. After partial removal of air from the headspace of the can by exhausting, mechanical vacuum, or a steam jet, the cans are permanently sealed. The cans after closing are usually heated at the temperature of boiling water to effect commercial sterilization.

In this sequence of operations, tissues of relatively high or low nutritive values may be removed and the carbohydrates content may be enhanced by addition of sugar syrup. Such effects are, however, frequently similar to home preparation of fruits for serving. The large size of the pieces tends to limit the leaching of water soluble materials from fruits during washing with cold water. Partial removal of oxygen from the can headspace by exhausting minimizes oxidative inactivation or destruction of ascorbic acid. The thermal stability of thiamin below pH 4.5 is such that inactivation of this factor during the thermal processing of fruits is quite low. This is clearly indicated by ascorbic acid values of 152 mg. before and 147 mg. per No. 2½ can of tomatoes after processing; also by thiamin values of 434 µg before and 438 µg after processing the sealed can 50 minutes in boiling water. These data were obtained by studies made during the current season.

CANNING JUICES

In the patterns followed in the production of fruit juices including tomato juice, the general procedure is roughly similar to that employed for canning fruits as large discrete particles with the obvious exception that the fruit is reduced to a juice by some suitable procedure. In the production of juice a definite sacrifice of provitamin A may be encountered in case the pulp of the fruit is not included in the juice. To-

mato juice and fruit nectars prepared from fruits containing appreciable quantities of provitamins A are mostly of the pulpy type. Hence the vitamin A activities of these fruit products are quite similar to those of the corresponding fruits.

The retention of ascorbic acid in canned tomato juice or citrus fruit juices appears to be dependent in large degree upon the degree of protection from atmospheric oxygen during extraction and other operations subsequent to closing the can. Under good commercial operating conditions the sacrifice of ascorbic acid accompanying the production of citrus fruit juices is practically negligible. However, in certain commercial operations in which oxygen may be incorporated in the juice during extraction and other operations which contributed to a low final vacuum in the can, definite decreases in ascorbic acid contents may be noted. Our experiences indicate that heat, *per se*, is a relatively unimportant factor from the viewpoint of ascorbic acid retention where reasonable precautions for exclusion of oxygen are observed.

CANNING PRODUCTS WITH pH ABOVE 4.5—LARGELY VEGETABLES

A third general pattern is that employed for canning vegetables (non-acid products with pH values above 4.5) as discrete particles. As in the case of all canned foods, the first steps include removal of extraneous materials by a sequence of cleaning operations. A pre-heating treatment known as a blanch or scald applied early in the canning of vegetables is an important factor influencing retention of nutrients in the finished product. This preliminary heat treatment performs a number of functions such as cleansing, shrinking bulky products so as to permit packing of proper or legally defined amounts of food in the can, expulsion of gases and inactivation of enzymes. However,

exposure to hot water or even steam⁵ may in certain circumstances result in a considerable sacrifice of water soluble nutrients through leaching. The extent of sacrifice is dependent upon a variety of factors among which are the type and maturity of the product, time and temperature of blanching, and the blanching medium. Data reported in the literature and substantiated by data obtained in our laboratory indicate that the loss of water soluble nutrients accompanying blanching operations may frequently be as high as 25 per cent. A portion of the water soluble materials in the vegetable pass into the liquid medium or "brine" in which it is customarily packed. This medium is, of course, contained in the can as delivered to the customer and to obtain full benefit of the nutrients which passed into solution, it is essential that this liquid be utilized.

Because of the relatively severe heat treatments used in sterilizing vegetable products there has been a tendency to regard the sacrifice of ascorbic acid and thiamin during thermal processing to be exceptionally high. In reality, under commercial operating condition, decreases in ascorbic acid accompanying the thermal processing of canned vegetables do not appear to be as great as many have indicated. Data obtained during the past season show that peas containing 82 mg. of ascorbic acid per No. 2 can (solid plus liquid) prior to processing retained 79 mg. per can after processing 35 minutes at 240° F. Ascorbic acid values per No. 2 can of cut green beans were 48 mg. before and 43 mg. after processing 20 minutes at 240° F. In the case of thiamin it is well established that partial inactivation of thiamin is to be expected during thermal processing of vegetables. However, published thiamin values for canned vegetables^{2, 6} indicate that the thiamin retention in canned vegetables may be rather high. Here again studies

made during the past season show that peas containing 960 μ g of thiamin per No. 2 can as filled retain 590 μ g per can after processing 35 minutes at 240° F. Non-processed cut green beans containing 210 μ g of thiamin per No. 2 can retained 170 μ g of thiamin after processing 20 minutes at 240° F.

The nutritive values derived from canned foods are influenced by the conditions under which they are stored. Although supporting analytical data are rather limited, it appears as if the vitamin contents of canned foods are well retained at usual room temperatures during periods consistent with common marketing practices. At higher storage temperatures (98° F.) the losses of ascorbic acid from at least some canned foods may be markedly accelerated. Hence, the storage of canned foods in cool places as is customarily recommended is to be desired.

The treatments which foods receive in the kitchen may also be important factors influencing the dietary values of canned foods as consumed. As suggested, the practice of utilizing the liquids as well as solids in the can pays good dividends in the form of water soluble minerals and vitamins. In fact, the concentration of ascorbic acid and thiamin in the liquids may equal or exceed that in the solids portions. Canned foods have been thoroughly cooked during production and require only a minimum of reheating after opening. It is therefore suggested that in case the food is to be served hot the solid portion of the vegetable be heated only to the desired temperature for serving.

CURRENT NUTRITION STUDIES

Detailed information regarding the nutritive values of canned foods and the effects of cannery operations on the nutrients in foods is still to be considered inadequate. However, during the first half of 1942 some 850

samples* comprising 28 fruits, vegetables, and marine products canned in the major producing areas have been assayed for provitamin A or vitamin A, ascorbic acid, thiamin, riboflavin, niacin, and pantothenic acid. In a special research program,* the distribution between solids and liquid in the can of thiamin, riboflavin, and ascorbic acid has been studied for fruit and vegetable products, and the effects of food preparation methods on these vitamins in canned vegetables have also been investigated. The results from this program already have been made available to the Armed Forces through the Food Composition Committee of the National Research Council. Publication of these data by the collaborating university groups is projected for the near future. The proximate composition and mineral contents of these 1942 samples are still under investigation at this time. Although this phase of the study is not completed, a substantial number of samples of the various products have been analyzed.

This program is also being continued during the current year, with the total number of samples scheduled for analysis somewhat curtailed. However, the program has been expanded to study the effects of cannery operations on retention of nutrients of the raw stock in the finished products. Such studies are being conducted in the field, working with materials as they are routinely handled in canning lines during commercial production. Data obtained from this phase of the program should assist

in establishing more precisely the extent of sacrifices of specific nutrients during canning, and indicate possible improvements in the operations associated with such sacrifices. It is anticipated that results obtained from these studies will point the way to the production of canned foods with even higher nutritive values.

SUMMARY

The energy, carbohydrate, protein, and fats derived from canned fruits and vegetables may be considered as being of slight nutritional significance. The chief nutritive values of these foods are associated with the vitamins and minerals they contain. Canned citrus fruits and tomato products are among the more valuable dietary sources of ascorbic acid. The provitamins A contained in canned leafy green and yellow vegetables constitute a major source of vitamin A activity in our diets. More concentrated food sources of the B vitamins and minerals are not found among the fruits and vegetables either fresh or canned. However, many canned fruits and vegetables contain important quantities of niacin, thiamin, riboflavin, calcium, phosphorous, and iron, nutrients which many diets supply in sub-optimal quantities. Certain differences in nutritive values found in different canned products are discussed.

Sanitary Engineering in Latin America*

LT. COL. HAROLD B. GOTAAS, SN.C., F.A.P.H.A.

Assistant Director, Division of Health and Sanitation, Coördinator of Inter-American Affairs, Washington, D. C.

THE scope of the sanitary problems which now confront the engineers of the Western Hemisphere is impressive; yet problems of greater magnitude and variety will surely be presented as air transportation, the Inter-American Highway, post-war economic relationships, and other developments bring the peoples of the western hemisphere more closely together physically, economically, and politically. More rapid communication, and the failure of disease to recognize political boundaries, are making sanitary problems, which were formerly confined to isolated areas, potentially common to most of the western hemisphere.

The western hemisphere has been undergoing a "sanitary awakening" which has paralleled economic developments. It took root and grew rapidly first in North America; that it is now growing among the peoples of the other American republics is evidenced by the inclusion of sanitation as an important part of their plans for future development. Future sanitary developments in the Americas will be expedited and facilitated by a close coöperation and understanding between engineers and other health workers, thus paving the way for an exchange of personnel, information, and experiences.

HEMISPHERE COÖPERATION IN SANITATION

International coöperation on public health problems has been sponsored by the International Health Division of the Rockefeller Foundation for almost a generation. This organization has demonstrated in many countries the social and economic desirability of sanitary projects. In addition, it has fostered the training of medical, nursing, and engineering personnel of the coöperating countries by bringing students to the United States and other countries for education and experience.

The Pan American Sanitary Bureau, which was formed by treaty between the American republics, has supported training programs for the development of talent in the field of sanitation. By providing advice, literature, and education to all the countries of the Americas its able field staff has done much to further sanitation on a hemispheric scale. The Pan American Sanitary Bureau is the product of true inter-American coöperation in which all countries are represented in a common program to improve public health in the Western Hemisphere.

At a conference of the foreign Ministers of the 21 American republics held at Rio de Janeiro in January, 1942; plans were made for a polyphase program of coöperation for the purpose of (1) greater development of the economic resources of the Western

* Presented before the Engineering Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 14, 1943.

Hemisphere; (2) the control of anti-American activities in the American republics; and (3) hemispherical defense of the Americas. The conference proposed that individual or coöperative action be taken to deal with problems of health and sanitation in the hemisphere, and suggested that such action should be undertaken in accordance with the ability of the different countries to provide raw materials, services, and funds.

Because of the necessity for quickly utilizing the resources of the Western Hemisphere, and for providing adequate hemisphere defense, both of which require health and sanitation operations to protect the people of tropical regions against the hazards of their environment, the difficult task of planning a coöperative program was immediately undertaken. The urgency of the program, its coöperative aspects, and the financial problems, made it necessarily a federal government project. In the Office of the Coördinator of Inter-American Affairs there was established a Division of Health and Sanitation, under the direction of Major General G. C. Dunham of the Army Medical Corps, who had had wide experience in health and sanitation work in both hemispheres. A corporate medium, the Institute of Inter-American Affairs, was created to serve as the legal entity for conducting the program.

At the present time coöperative health and sanitation programs are under way in 18 of the Latin American republics. The work includes construction and initial operation of hospitals, health centers, and dispensaries; development and rehabilitation of water supplies; construction and extension of sewerage systems; malaria control through drainage, larvacidal operations, and atabrine distribution; education of medical, engineering, and nursing personnel, and education of the public in health. The health pro-

gram in the respective countries is carried on as a coöperative service, usually called "Servicio Cooperativo Inter-Americano de Salud Publica," and is a part of the government of the host nation. All authorizations for projects, and matters of policy, must be approved by a representative of the host government and by the Chief of Party who serves in a dual capacity as Director of the "Servicio" and representative of the United States Government. The Chief of Party is either a physician or a sanitary engineer. As far as possible the "Servicio" is staffed with national personnel; the Institute of Inter-American Affairs provides the necessary North American personnel for supervision and technical guidance. The basic Institute or United States personnel are a physician, an engineer, and a business manager, although it is usually necessary to have a larger field group.

Both of the coöperating governments contribute to the costs, and a definite plan is made for the host government steadily to increase its financial support and for the Institute of Inter-American Affairs to decrease its contributions until the host government completely takes over the public health program. Plans were made for the Institute to assist in developing national professional personnel to take over the health and sanitation work as soon as practicable. Since the final success of any public health program depends upon the caliber and number of qualified personnel in the country, the Institute, therefore, is sponsoring training in the United States for medical, engineering, and nursing personnel who are devoted to their country and the cause of public health. As national personnel become qualified to carry on the work, the Institute men are removed. Thus, in addition to the part played by health and sanitation in the development of the economic resources of the hemi-

sphere and the defense of the Americas, the level of health and sanitation in the Americas will be raised. As the plan is now conceived, each host government will have qualified personnel to carry forward the long-range public health programs.

STATUS OF SANITARY ENGINEERING

Although in some parts of the Western Hemisphere sanitary engineering is a young but growing branch of the engineering profession, there are still many places where it grades through childhood and infancy to the embryonic stage. In the United States the sanitary engineering profession has developed rapidly during the past 25 years, until it now contributes an important part to all public health and public works programs. The progress and growth of the profession in Latin America has been less rapid. Nevertheless, one may see in the other Americas some fine engineering works and will meet there many very able engineers. Some countries have excellent sanitary engineering staffs in their health departments. In general, however, sanitary engineering is just getting started and has not yet played an important part in public health work. Reasons for this are: first, public health has only relatively recently received emphasis in social thinking; and second, there is a great scarcity of engineers in Latin America and they find higher salaries in private work and branches of engineering other than sanitary. The increased economic development, including building, transportation, and industrial expansion, in which the engineer has taken a leading part, has allowed little professional interest on the part of engineers in sanitary work. Because of this situation, the educational institutions and the authorities responsible for public health are not familiar with the rôle and functions of the sanitary engineer. Hence, there

has been neither much demand for, nor promotion of, the profession. When a few sanitary engineers have been trained, the results of their work and their very presence will encourage and further the development of the profession.

The social status of the professional engineer in the other Americas is very high. On graduating from an engineering school, he receives the Doctorate title. However, he prefers to be called engineer. In general, the salaries of engineers in the other American countries are the highest of the professions. Latin American engineers have a background of experience which could well be exchanged with North American engineers to their mutual advantage. North American engineers working in the other Americas often find methods and practices which are not consistent with their experiences. Before deciding that theirs are better, they should carefully investigate the reasons for the practices, because often there is validity in the practice. There are registration boards for professional engineers in many Latin American countries which require that foreign engineers must become registered in order to practice in the country. Hemispherical coöperation in the engineering profession will increase the contribution of the engineer to society.

SANITARY ENGINEERING WORKS

1. *Water Supply and Purification*—For several years the United States has had standards of water quality which have been the accepted measuring stick throughout the country. In Latin America such standards for water quality have not yet been used on an extensive scale largely because of the shortage of sanitary engineers in health work.

Although there are public water supplies in Latin America of which many comparable North American cities would be proud, the development of

safe clean water supplies remains the most critical sanitary problem confronting the other Americas. Many relatively large cities do not have safe water and many smaller cities have as yet been unable to develop a public water supply. Boiling of the water is the accepted precaution used by people who are familiar with the hazards of contaminated water. As well as being a health problem, water supplies in many areas are a very important economic problem. Communities are built on streams which are often the avenue of transportation. In some places the poorer people must spend two hours or more early in the morning carrying the day's water requirements from a polluted stream before they start the work which earns their livelihood. The streams, as well as being the source of water, are often the public laundry and the natural channels for waste disposal.

Slow sand filters have been used more commonly than the rapid type because of the high cost of chemical coagulant and the need for simplicity of operation. North American water plant design practice is probably as common as European practice, although European equipment is used more extensively. Because of the shortage of chlorine, chlorination equipment and shipping facilities, only the large cities are able to chlorinate their water supplies adequately. The maintenance of a desirable residual throughout the distribution system is uncommon. The pipe sizes in distribution systems are generally smaller than those used to serve cities with populations of similar magnitude in North America. One reason for this is that fire protection is less important in the unheated buildings of the warmer climate. Fire protection is not needed for the better class of buildings which are constructed of concrete, brick, and tile, and it is cheaper to replace the poorer class buildings than to protect them. The

pressure carried in the distribution system is lower than is common in North America. The low pressures and poorly maintained distribution system are often responsible for contamination of water which may have left the treatment plant clean and safe. Because the demand for water often exceeds the capacity of the system, the water is turned off during the night. Consumer pumping creates low or negative pressures and serious contamination of the mains. Cross-connections are a very serious source of contamination of water supplies in many cities. Since water meters are not often used except for large consumers, there is considerable waste of water.

Hydrological information on stream flow or on ground water sources is very limited. Ground water will no doubt prove to be the principal source of supply for smaller cities. Future plans of several American countries include investigation and development of ground water. A sincere, keen interest in safe water supplies exists in the Americas. In many places supplies are projected for construction as soon as materials and equipment become available. The writer believes that the post-war period will witness rapid progress in water supply development in the other Americas. Financial problems in small cities and the inability of the consumers to pay the cost of water and service connections will present difficulties. In contrast to public water supplies in North America, which often started from a small beginning and were expanded from earning and short term loans, many Latin American cities that have no public water supplies will have to finance a large initial outlay. These difficulties may be offset by the fact that in many countries there is centralized government control of the planning and financing of public works.

2. Sewerage and Waste Treatment— Except for large cities in the other

Americas, there are few facilities for the sanitary disposal of excrement. Even latrines and privies are uncommon in the poorer areas, and the incidence of intestinal diseases in these areas is therefore very high. Sanitary disposal of excrement is a primary health problem in many places and must be accomplished before hookworm and other intestinal diseases can be controlled since the people are immediately reinfected after treatment.

Since the development of sewerage facilities usually parallels or follows water supply development, only the larger cities are sewered. Although there are some good sewage treatment plants in Latin America, sewage treatment is the exception rather than the rule. Large cities are generally located on the coast or on streams where sewage disposal without treatment is satisfactory. In these areas it is doubtful that sewage treatment will make very rapid progress. In the arid coastal regions of western South America, where every drop of water is valuable, sewage is discharged into irrigation ditches. The incidence of intestinal diseases is usually high in these localities. Since irrigation with sewage is an economic necessity, many treatment works are being planned and, in the future, the treatment of sewage will probably be standard practice in this area. It is believed that the use of mechanical equipment in sewage treatment has been overdone in North America, and that it will be used less extensively in the other American republics as their sewage treatment program develops. Design practices for sewage treatment in Latin America will differ from those in the United States because of the climate, and the quality and quantity of wastes.

3. *Refuse and Garbage Disposal*—Land-fill is the most common method of garbage disposal in the other Americas. Excellent progress has been made with the use of sanitary land-fill in sev-

eral places. In others the garbage dump becomes a breeding place for flies and rodents and a feeding ground for scavengers. The garbage and refuse is usually fairly dry, and the quantity per capita is much less than in the United States. While incineration is used in many places and may be used almost as satisfactorily as in the United States, it is not as economical as sanitary fill. Sanitary fill, in addition to being a method of disposing of refuse, can be used for reclamation for low-lying lands and filling swampy areas which are foci of mosquito breeding. In fact, sanitary fill may be operated more satisfactorily in most of the Latin American countries than in the northern part of North America because of the more or less uniformly warm climate.

4. *Mosquito Control*—The control of mosquito-borne diseases, particularly malaria, is probably the greatest health and sanitation problem in the tropical and semitropical areas of the Western Hemisphere. Malaria control assumes great economic importance in the development of natural resources. Air transportation has greatly increased the possibilities for spreading the different malaria vectors from one area to another. Also, the other mosquito-borne diseases such as yellow fever, dengue, and filariasis, which exist in scattered areas throughout the hemisphere, may be spread by the air transportation of infected mosquitoes. Considerable information is now available, and new data are being gathered on the identification, distribution, and biology of the different malaria vectors in the Americas.

In the other American republics sanitary engineers have had a very small part in mosquito control activities. Mosquito control, including drainage, larvacidal spraying, screening, etc., is usually conducted under the direction of a physician who has a staff of inspectors. This system has operated

fairly satisfactorily for temporary control, but leaves much to be desired in permanent control and drainage.

Drainage and filling are probably the most effective means of controlling the malaria around large cities in Latin America. Drainage ditch lining with precast concrete is practised extensively. The Panama invert is used most commonly in Central America while in South America the one-half or one-third precast concrete pipe invert is used. In El Salvador vitrified clay Panama inverts have been installed satisfactorily and very economically. Mosquito control by fluctuation of the water level through the use of dams and siphons has been practised satisfactorily in Bolivia. However, in rural areas, or places where the topography is adverse, drainage may be much too expensive.

Screening is very important in semi-tropical rural areas where the houses can be efficiently screened, but it is not effective for thatched and mud wall huts. In the future, economical and efficient use of mosquito repellents may be found to be helpful in controlling mosquitoes under conditions where drainage and temporary larvicidal operations are unsatisfactory. Since mosquito-borne diseases are closely associated with climate and topography, and since improvement of environment is an important method for lessening the mosquito-borne diseases, the sanitary engineer's interest in the control of these diseases should be continually increased.

5. *Housing and Slum Clearance*—The field of housing has recently become a public health problem of the sanitary engineer. As the standard of living increases, housing and slum clearance become more and more important. Provisions for improved housing and sanitation are included in the progressive social security legislation of several of the Latin American countries. Excel-

lent results with housing have been demonstrated in many areas. For instance, in Brazil I was impressed by the very interesting plan for slum clearance which has operated successfully. Under this plan, slum and blighted areas are purchased from the owners by the government, and are replotted in accordance with the city plan. After streets and utilities have been provided, the original owners are given the first opportunity to repurchase the property. The increase in the value of the property usually pays for the utilities and streets. Further development of the property in these areas must be in accordance with the city plan.

In Colombia rural housing is carried on by a government housing authority which builds homes for rural families. The cost of the home is amortized by monthly payments over a period of years, and provision is made for cancelling the unpaid balance in case the head of the family dies. Thus the heirs receive the home free of debt. Elsewhere in the Americas plans for providing housing are being and have been carried out successfully.

6. *Industrial Hygiene and Sanitation*—Excellent social legislation designed to improve health conditions of the worker has been developed in many of the Latin American countries. Because of the shortage of labor and increasing industrial development, industrial hygiene and sanitation will be utilized as an economic means of obtaining greater production from their man power. A few countries now have occupational disease control programs. However, at the present time sanitation and general public health appear to be more important than specific control of occupational diseases.

SANITARY ENGINEERING EDUCATION

Education, both for developing personnel in the field of sanitary engi-

neering and for the general education of the public concerning sanitation, is of primary importance in all parts of the Western Hemisphere. During the past decade, in the United States sanitary engineering education, particularly on the postgraduate level, has increased greatly. It would appear that as long as the 4 year program of our engineering schools continues, the major part of sanitary engineering and public health education will have to be given as postgraduate study.

Engineering schools are established in almost all of the other American republics. They are usually housed in good buildings, and have eminent engineers on their faculties. Most of the faculty members are engineers who teach part time and engage in private practice or work for government departments. The engineering curriculum varies between 5 and 7 years in length, but is usually 6 years. Little attempt is made to specialize in different branches such as civil, electrical, and mechanical. Major emphasis in their program is placed on civil engineering. Only a few schools give any training in sanitary engineering, and the majority of the courses deal with water supply and sewerage design. A few universities, notably the National University in Peru, have recently started more extensive training in sanitary engineering as a part of the 6 year engineering course.

In the past French and German textbooks have generally been used, but today North American texts are filling the libraries. A transition is now in progress from the European type of highly theoretical engineering education to the American approach which stresses the practical application of theory. Very little training in environmental sanitation and sanitary engineering is provided in the schools of public health in Latin America. Because of the scarcity of engineers and the failure of schools of public health to

include training in sanitation, engineers do not attend them.

POST-WAR SANITARY ENGINEERING

The post-war opportunities for the sanitary engineer to serve humanity throughout the world will certainly not be lacking. Future public works and public health requirements in the field of sanitation and sanitary engineering in the United States will no doubt be large. Industrial wastes and stream pollution control on which considerable planning and study was accomplished prior to the war probably will be undertaken on a large scale in the post-war period.

It is believed that sanitary engineering in Latin America will receive great impetus after the war. There is much sanitation to be done and sanitary engineering, as such, is in an early stage of development in most Latin American countries. Safe water supply, sewerage, malaria control, and general sanitation will be developed as rapidly as is economically possible. Economic development of the resources in many Latin American countries is very closely associated with sanitation, thus requiring progressive sanitation in order to realize the full advantages of their resources.

The services of the engineer can well be utilized in the fields of public health administration and planning. Thus far in the development of public health, we as engineers have generally played a small part in administration and the forming of public health policy. We have tended to remain as technicians in our specialized fields without having sufficient influence on the over-all policies of public health administration. The administrative ability of the engineering profession has been recognized generally in other fields and it is believed that recognition in the field of public health will follow, opening new avenues for the sanitary engineer.

The Case Method in Teaching Public Health Administration

HAROLD D. CHOPE, M.D., DR.P.H., F.A.P.H.A.

Member of the Staff of the International Health Division of The Rockefeller Foundation, New York, N. Y.

DURING 1940-1941 the author was engaged upon a general study of the problem of making public health administration a more effective part of the graduate school curriculum in public health. The task is an old one: i.e., an effort to place an applied subject on an equal intellectual footing with older disciplines which depend for their intellectual attractiveness upon the experimental method and the achievements of that method.

After reviewing past experience and current opinion regarding education in public health administration, it was decided that there were available five teaching methods which can be described as follows:

1. The lecture and assigned reading method
2. The seminar method
3. The apprentice method
4. The dig-it-out-yourself method under proper guidance and criticism
5. The case method

Each method has its own advantages; and public health administration may be taught by all of these methods, by anyone, or by any combination. The method or methods selected depend on several factors: the personality, experience, ability, and energy of the teacher; the number of students in the class; the availability of well organized field areas; the relationships between the academic institution and the local or state public health organization.

The *lecture method* is the least satisfactory and perhaps one of the most commonly used methods of teaching public health administration. Indeed, a lecture has been described as "the process by which the professor's notes become the student's notes without passing through the mind of either!" The lecture method certainly has its place. For the instruction of large classes, for the presentation of certain historical data, for descriptive analyses, and in providing general background for other types of study, it is essential. It is probably the easiest method for the professor, because he can prepare his lectures and, if he is so inclined, read them to the students year after year with minor changes. From the viewpoint of the student, the lecture and assigned reading method tends to place more emphasis and a higher premium on memory and knowledge of the lecture notes than on cerebration and critical analysis.

The *seminar method* is less formal: it allows for an exchange of ideas between the professor and student and, more important, permits student participation in the development of an idea or a subject. This method is used extensively in schools of public administration. Its disadvantages are that it works successfully only in small groups, preferably not more than ten, and that the professor has to possess the particular ability to incorporate

the student's ideas and approaches into his teaching; for, unless expert guidance is given to the seminar, all hope of a systematic discussion of a topic is lost.

The *apprentice method* is claimed by many to be the only method by which administrators may be trained. Persons of this belief feel that the qualities needed by a successful administrator can be developed only in the face of the necessity of making clean-cut decisions, and that any other type of training is vicarious, sterile, and non-productive. It is perfectly true that other professions, such as medicine, have found that even an extended period of classroom and laboratory experience does not produce a finished product, and that a period of apprenticeship or internship is required before the student is capable of practising his profession. A period of supervised employment of students after completion of a graduate academic year would undoubtedly be of value in the development of public health administrators, but the actual inauguration of such training, except in a few localities, has been deterred by many factors. Because of the present shortage of personnel, state health departments or other agencies sponsoring public health fellowships are anxious to have the student return to his regular appointment as soon as possible after completion of the academic year. Once the student returns to his job the school has little opportunity to exercise any control or supervision over his activities, and frequently the health department is more interested in his immediate usefulness than in his continued development. The average local or state health department is not prepared to take interns for short periods and integrate them into their regular program activities, sharing the supervision of the intern's program with the university. Frequently the intern serves

only as an interested observer instead of an integral part of the organization, and too great a variety of experience is arranged.

The *dig-it-out-yourself* method under competent guidance is probably the most effective teaching technic and is the exact opposite of the lecture or "spoon-feeding" method. When taught by this technic, the student is assigned a problem and it is up to the individual to orient himself, set up his hypothetical questions, accumulate his data, analyze them, and propound possible solutions. This method usually establishes an intimate bond between the student and his faculty adviser, provides opportunity for wide reading, and frequently extensive field contacts. However, the students of public health administration could undertake only a few problems in the course of an academic year, as this method of learning is most time-consuming and is usually reserved for the advanced student who is a candidate for the degree of Doctor of Public Health.

It is the object of this brief communication to discuss the *case method* and report on a single experience which seems worthy of record.

Case study is not new. It originated in the Harvard Law School and has extended through law schools into schools of business administration and more recently into the field of public administration. In a sense this method has always been used in teaching medicine. Since the days of Hippocrates, students of medicine have learned to manage the patient of today through consideration of the history, examination, and progress of the patient of yesterday as his condition was unfolded by the successful medical teacher.

The success of the case method in the teaching of law would seem to depend on the fact that to solve a given problem the student has to use his knowledge and his independent

ability in marshalling decisions and precedents which apply to it. In many respects this is the experimental approach. The student is confronted by a question which he answers by a more or less competent use of his past experience. Similarly, in medicine the student confronted by a problem in diagnosis and treatment must, to reach his conclusions, resort to his memory of previous patients, reinforced by his knowledge of chemistry, bacteriology, and pathology.

In defense of case studies as used in other branches of education, the following quotations are cited:

Wallace B. Donham, Dean of the Harvard School of Business Administration, states: "The failure of both business and political leadership to rise to the heights needed has its roots, I believe, in the failure of our universities to prepare men broadly for the world of affairs. The only way these things can be attempted in our universities without resulting in a vast amount of unrealistic sentimentality is, I believe, by paying more attention to the great intellectual field of administration. The theory and action must meet; their decisions must be efforts to do the best one can under all the circumstances. The administrator must integrate, decide and act—the one way to train men for administration is by the case system and, so far as I know, there is no other classroom method which impels students to go through the mental processes involved in administration."¹

Professor George Graham has made the following comment: "Three factors lay at the root of the case system's development. One was the conviction that administration was essentially the solution of successive problems; that the administrative process was one of gathering all relevant information bearing on the problem, making decisions and carrying them out. The second factor

was the demand for a device to interest and stimulate the active, extrovert type of student who had ample energy, but not too well developed study habits. The third factor was the desire to avail students of all fields of knowledge relevant to their problems regardless of existing lines of university organization. The case is thus a practice problem, a disciplinary device, and a means of integration."²

William E. Mosher finds even greater implications in the case system as a research method: "Case studies, in and for themselves, may have some suggestive value, but unless they cover systematically and comprehensively all possible variations with respect to one or another feature or problem no generalization can result. It is the hope of establishing generalizations, of discovering dependable and predictable relationships and sequences that ever beckons the scientist on. He believes that there is order in the universe and has confidence that through patient inquiry, painstaking observations, and the reasoning process of the human mind this order may be discovered."³

On the basis of these opinions it was decided during the second semester of the academic year under consideration to try out the case system in connection with the teaching of public health administration. Following the outline of case studies of the Committee on Public Administration of the Social Science Research Council, the students were asked to prepare case studies drawn from their own experiences. This work was done on a voluntary basis, and the presentation and discussion of the cases took place in the evening.

THE EXPERIMENT

The following plan for an exercise using the case report method was submitted to the students:

1. Each student is requested to describe a problem in public health administration (ac-

tual or hypothetical) that has been of interest to him.

2. These will be submitted to the faculty of the department of public health practice and the best and most illustrative cases will be selected for class discussion.

3. The case reports selected will be duplicated and distributed for consideration by the students prior to the meeting.

4. The faculty and students will discuss each case presented and attempt to arrive at a decision.

OUTLINE FOR WRITTEN PRESENTATION OF A CASE REPORT

Title: The title should be short and give the general idea of the material covered, e.g., "Selection of Temporary Personnel."

Statement of the Problem: This should be brief and to the point.

Relevant Facts: Give as much background as is necessary to enable the group to outline possible decisions and select a course of action.

The Results: Do not include the decision which was made in the situation discussed or the results of the decision. This will be left for faculty and student discussion.

Twenty-five cases were submitted by the students. These were read and the most illustrative selected, edited, and duplicated. Because of the limitations of time only 8 cases could be selected and only about 15 minutes allowed for presentation and discussion. Four students were assigned to discuss each case. The titles of the 8 cases were as follows:

1. Promotion of a Staff Member on Basis of a Civil Service List
2. Development of an Esprit de Corps in a Disorganized Health Department
3. Direction of an Antagonistic, Politically Strong Bureau Chief
4. Local Public Relations
5. Disciplining of Subordinate Staff Member for Aggressive Self-promotion
6. Selection of a Location for a Health Department
7. Public Relations Involving the Medical Society and County Supervisor
8. Coordination of Activities of a State

Health Department to Avoid Duplication of Field Visits

Two cases which are fairly typical of those submitted and which gave rise to the most heated discussions are included here as examples. That the students expressed interest in these problems need not be doubted.

Case 6

Title: Selection of a Location for a Health Department.

Problem: Should the offices of a county health department be located at the county seat or in another city offering greater conveniences?

Relevant Facts: A county health department is to be organized in a county of 20,000 persons in which there are two principal towns, A and B. A, the county seat, has a population of 800 persons and is situated near the southern border of the county. There are two physicians practising in A—an older man over 65 years of age, who has been hostile to the proposed health department, and his assistant, who is 4 years out of college. The only building in A with central heating is the courthouse, in which there is no space for the health department.

Town B has a population of 7,000 persons and an additional 5,000 are to move in shortly to work on a dam, which is to be three miles from Town B. Six doctors practise in B. Three of them have a successful clinic and a 15 bed, closed hospital. Dr. M, the organizer of the clinic and hospital, has previously opposed the health department. The County Court having now authorized funds for the health department, Dr. M pledges full support and offers to build a \$10,000 building on a site one block from his hospital and four blocks from the main street of the town. He proposes to rent this building to the health department for \$30 a month. The three other physicians in B are lukewarm toward the health department and hostile toward the clinic group headed by Dr. M. Because of the influx of dam workers, office space is at a premium in Town B.

There are four other physicians in the county. One who lives 5 miles from Town A is violently opposed to the health department; he has not the professional respect of the other physicians. The remaining three physicians, who live within a radius of 10 miles of Town B, have pledged their support to the health department. Town B is located near the geographic center of the county, 20 miles

north of A. The budget is slender and has been appropriated for one year only. The Court has pledged support for a permanent health department if the experiment is successful. The county officials want the health department in Town A. All the physicians, with the exception of three, have signed a petition that it be in B.

Questions: Should the health department be located in Town A, the county seat, or in Town B?

Should Dr. M's offer to construct a building for the health department influence the decision?

Case 7

Title: Public Relations Involving Medical Society and County Supervisor.

Problem: What action should a local health officer take when an influential member of the County Board of Supervisors requests the violation of a policy established by the local medical society?

Relevant Facts: For a period of ten years or more the health department of a county situated in a southern state had been administering rabies vaccine without charge to any residents exposed to rabies. Recently a member of the local medical society objected to this practice. He contended that the health department should do only work which affected the health of the public and that rabies endangered the public in no way. He cited the fact that the health department did not administer tetanus antitoxin.

The matter was brought up before the medical society for discussion and the society went on record by a unanimous vote to request the health department to discontinue the administration of rabies vaccine, and further unanimously agreed that they would administer all necessary vaccine, charging a fee for those able to pay and giving it free to those unable to pay. The medical society assured the health officer that no one needing treatment would be deprived of their services and the health officer agreed to abide by their request.

Two weeks later, a local woman came to the office and requested rabies vaccine, having been bitten by an apparently rabid dog. The health officer explained to her the arrangement with the local physicians and she left the office. That evening the oldest member of the County Board of Supervisors (who are responsible for health department appropriations) called and asked the health officer to give the woman rabies vaccine. The supervisor stated that he would telephone to the state health officer if the local health office

failed to comply with his request. In the state in question, local health departments are under the direct supervision of the state health department.

Questions: What course should the local health officer follow at this point? Remember, he must make an immediate decision while talking on the phone with the supervisor.

What could have been done to prevent such a situation (a) at the time of adoption of the policy, (b) at the time of the woman's call at the health office?

After the case had been presented by the author the three students assigned to discuss the case expounded their ideas, an effort being made to obtain as many divergent viewpoints as possible. The author then told the actual decision that had been made in the case and the results, and during the remaining time the problem was thrown open for discussion by the entire class and faculty members present.

In the first case above described, the students who had had some experience with political organizations and county health service, maintained that the headquarters of the health department should be located in town A with the other county offices; while students with somewhat less experience held that the best service could be provided for the greatest number by locating the health service in town B. The class was nearly unanimous in agreeing that Dr. M's offer should not be accepted. The decision actually made was to obtain one room in the courthouse in town A which was considered the headquarters, and establish in a rented house in town B a branch health center.

In the second case described the discussion centered more on criticism of the health officer for allowing such a situation to arise than in a discussion of the possible solution.

The reaction of the students to these problems was enthusiastic; in fact, the most serious difficulty encountered was in attempting to limit the discussions

to the time available. Discussion of some of the cases was carried on among the students outside the classroom for some days after the exercise. It was observed that several students who had taken little or no part in classroom discussions defended with considerable ardor their viewpoints regarding the cases. In some instances students cited material learned during the regular course in analyzing situations, indicating a desirable integration between theory and practice.

It should not be understood from the foregoing discussion that the writer feels the case system is the *sine qua non* for the teaching public health administration. It is only a valuable aid. Education is not accomplished merely by having a problem to solve. Before the student can use case reports effectively, he must have a broad general knowledge of his field. This the case system does not provide. The case system may be very valuable in devel-

oping the capacity for decision in students and teaching them the tricks of administration, but it is no substitute for a thorough knowledge of the theory, principles, and philosophy of a subject. Teachers of administration must in some way find the golden mean between theory and precedent on the one hand and cases and cleverness on the other. Used alone, the case system would not produce the type of administrators that the schools of public health are anxious to turn out. Used as an adjunct to other methods of teaching, it might do a great deal to improve the interest and content of the present courses in public health administration.

The Epidemiology of Cancer

From the Viewpoint of the Health Officer*

MORTON L. LEVIN, M.D., DR.P.H., F.A.P.H.A.

*Assistant Director, Division of Cancer Control, New York State
Department of Health, Albany, N. Y.*

ACTIVITIES in cancer control by public health agencies need not and usually do not rest upon the recognition of any epidemiological peculiarities of the disease, in the strict sense of that term. The necessity for persuading people who have symptoms to seek medical care without delay, as well as the desirability of making it easy for them to secure prompt diagnosis and adequate treatment, are sufficiently well defined to furnish a secure foundation for public health action. It is recognized that to accomplish these objectives with some degree of completeness is an undertaking of considerable magnitude, particularly if all persons who reach adult age must be included in the scope of the cancer program.

Because the task of reaching the entire adult population with any type of control measure is manifestly great, the health officer who plans a cancer control program seeks to make the limited forces he can throw into the field count for more than may be expected of random action directed to the public at large. From experience in the control of infectious disease it is evident that information regarding what people are most apt to develop cancer or certain kinds of cancer would

be of value in the application of cancer control measures. The health officer who is interested in cancer control must also take stock of the modern advances in the etiology of cancer and inquire whether these now have any practical significance in the control of human cancer.

To review broadly the salient features regarding the occurrence of cancer in man, the facts to be considered may be classified under four general headings: (1) environmental or exogenous agents causing cancer; (2) the association of cancer with other diseases; (3) evidences regarding intrinsic or constitutional factors affecting cancer incidence; and (4) certain aspects of differential mortality.

It should be stated at the outset that cancer of different parts of the body and of different pathological character in the same part are different diseases. Although for some purposes it is useful to consider all types of cancer together, throughout this discussion differences in etiology and in epidemiological features according to site of cancer will appear.

EXOGENOUS AGENTS CAUSING CANCER IN MAN

Attention in the laboratory investigation of cancer is now focused on the rôle of chemical carcinogens, and of x-ray, radium and ultra-violet radiation in the causation of malignant

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-second Annual Meeting in New York, N. Y., October 12, 1943.

tumors. In human cancer such agents have been identified chiefly in the small group of occupational cancers. The first such observation was made in England in 1775 by Percival Pott¹ who noted in chimney sweeps a greatly increased incidence of scrotal epithelioma, caused by exposure to soot or some chemical contained in soot. The substances or agents now known to cause cancer in man include arsenic, tar, pitch, paraffin, petroleum oils and derived products, benzol, aniline dye compounds, roentgen rays, radium rays and ultra-violet rays, possibly asbestos, nickel carbonyl and chromates. What common property of these diverse chemicals and radiations makes them potentially carcinogenic is not clear; possibly all act by interfering with cellular enzymes, as the work of Rhoads² suggests. Most of these agents produce skin cancer. Aniline dye compounds cause chiefly cancer of the bladder; excessive exposure to radium salts has been known to cause bone sarcoma and carcinoma of the lung; leukemia may follow chronic benzol poisoning. With but few exceptions, the carcinogenic effect of these agents has been demonstrated in experimental animals as well as in man.

A survey of occupations listed³ according to exposure to various hazards shows 146 different occupations in this country in which exposure to known carcinogenic agents may occur. However, the number of reported occupational cancers is quite small. Hueper⁴ estimates that the total cases reported in the world literature is from 8,000 to 9,000, of which approximately 400 have been reported from the United States.

A partial explanation for the small number of reported cases of occupational cancer may be the fact that, although the period of exposure necessary to produce cancer may be as little as one year, the time from such expo-

sure until the appearance of the tumor may be as long as 30 years, averaging for some agents approximately 16 years, so that the tumor may not appear until long after the worker has changed his occupation. There is also a natural reluctance on the part of industrial management to release information on occupational cancer. Although preventive measures, including periodic examinations, have been adopted in some plants, especially in the aniline dye industry, often the hazards are not recognized or not properly guarded against. Exposure to aniline dye compounds occurs not only in the dye industry but in many others, including plants handling rubber and those manufacturing explosives. It is probable that the number of occupational cancers is greater than indicated by identified cases and that the enormous expansion of certain industries may further increase this number in the future.

Obviously, exposure to the carcinogenic chemicals and radiations need not be occupational. Arsenic cancer of the skin has been observed following prolonged medicinal administration of Fowler's solution and, in the Argentine, from drinking water contaminated by arsenic ores. The influence of ultra-violet radiation is believed responsible for the higher general incidence of skin cancer in the South as compared with the North in this country, as well as for its high incidence among outdoor workers in the North.

The relationship of carcinogenic chemicals and radiations to the common run of malignant tumors in man is a matter of speculation. It has been suggested that part of the increase in cancer mortality of modern times may be attributable to the increased exposure to such substances accompanying the industrial age. The difficulties in the way of testing such a hypothesis may be appreciated from the fact that a chemically induced

tumor does not differ histologically from one arising in the same organ apparently spontaneously, and that such a tumor may appear long after the chemical agent has been eliminated from the body.

We may anticipate that a great deal of future investigations on the causes of cancer in man will center on the possible presence of chemical carcinogens in food, water, and dust. Although the significance of the known carcinogenic agents in the etiology of the vast majority of human cancers is at present unknown, continued medical observation of workers exposed to carcinogenic agents, even after they have left the employment where such exposure occurred, is clearly indicated. This is rarely done now and presents a field for possible public health action.

DIFFERENTIAL CANCER MORTALITY AMONG SOCIAL-ECONOMIC GROUPS

In addition to the small group of identified occupational cancers, a considerable array of statistical evidence points to increased mortality from certain forms of cancer in those economic groups among which industrial workers are largely found.

Stevenson⁵ analyzed cancer mortality statistics for males in England and Wales on the basis of social-economic class, dividing the population into professional workers, skilled workers, unskilled workers, and two intermediate groups. A progressive increase in cancer mortality was found in each "lower" social-economic group. This increase was confined to cancer of the skin, lip, larynx, and the alimentary canal from mouth to pylorus. For these sites, the standardized rates in unskilled workers was twice that of professional workers. In married women, classified by husband's occupation, a similar though less marked relationship appeared for the same sites of cancer and also for cancer of the uterus, indi-

cating that factors other than those due directly to occupation must be considered in explaining these facts. In married women also, a reverse relation was found for cancer of the breast, ovary, and thyroid, in which the higher rates were in the higher classes. The same differences appeared among single females, classified by social-economic status.

In this country, broadly similar findings have been reported by Knight and Dublin⁶ in life insurance data, and by Whitney,⁷ for total cancer not subdivided according to site. In Massachusetts, Lombard and Doering⁸ found that the foreign born and those of foreign parentage had higher mortality rates for buccal cavity and stomach cancer, but not for other sites. They concluded that a sufficiently close relationship exists between these nativity groups and the lower social classes of England to justify the opinion that economic social conditions are a factor in the incidence of cancer. It is of interest that the first analysis of cancer mortality by economic status in this country was made by Charles V. Chapin⁹ on the mortality returns of Providence, R. I., for 1865. He found the rate twice as high in the lower as compared with the higher economic class.

Greater diagnostic accuracy in the medical care available to the higher income groups does not readily explain these differences in cancer mortality in social classes for the reason that better diagnosis increases rather than decreases the total number of recorded cancers. Also the types of cancer in which the differences are found include both easily diagnosed sites, such as the skin, and poorly diagnosed sites, such as the stomach. Moreover, one of the most accurately diagnosed forms of cancer, that of the breast, shows opposite social selection to that observed for almost equally easily diagnosed sites, such as the lip, the buccal cavity,

and the uterus. Better therapeutic results might explain lower mortality from skin and lip cancer in the higher economic groups, but not lower mortality from esophageal and stomach cancer, and certainly not the higher mortality from breast cancer in these groups. The differences in cure rates for stomach cancer in the best clinics as contrasted with the average would be insufficient to account for differences in cancer mortality as pronounced as those observed.

The findings with respect to the higher cancer mortality in unskilled and industrial economic groups are frequently cited as evidence that the living conditions of these groups involve greater exposure to "exogenous carcinogens." Aside from specific occupational carcinogens, we are unable to identify what these agents may be.

Regardless of the explanations for the higher mortality from certain forms of cancer in unskilled and industrial workers, the need for concentrating attention on such groups in applying cancer control measures is evident.

ASSOCIATION OF CANCER WITH OTHER DISEASES

It has long been noted that cancer occurs more frequently than normal in tissues the seat of the so-called precancerous lesions. The evidence for significant association is often far from conclusive. Precancerous lesions have been described in the skin, lip, liver, mouth, bones, thyroid, gastrointestinal tract, breast, ovary, uterus, and vulva. The greatest number have been described in the skin, where at least twenty-two different precancerous states are said to occur.¹⁰ It should be noted that in most cases of cancer, a specific precancerous lesion cannot be identified.

The subsequent incidence of cancer in persons with precancerous lesions varies greatly, from a few (xeroderma pigmentosum; erythroplasia of Queyrat)

in which cancer always supervenes, to many in which it is only an occasional occurrence. For the most part, figures which are reported refer not to secondary incidence but to frequency of association. Where secondary incidence is stated, the factors of age and duration of observation are usually not taken into account. For most precancerous lesions, the available information does not permit accurate estimation of the degree of increased risk of cancer which they carry.

There is adequate evidence that in women with chronic cystic mastitis¹¹ the subsequent incidence of breast cancer is from 2 to 10 times as great as the average. Epithelioma of the tongue occurs in syphilitic males about 5 times more frequently than would be expected normally, and recently there have been presented data¹² indicating that a similarly high incidence of cervix carcinoma occurs in women who have had syphilis. Other conditions apparently associated with subsequent cancer which may be mentioned are multiple polyposis, with intestinal cancer; cirrhosis of the liver with primary liver cancer; Paget's disease of bone with osteogenic sarcoma; atrophy of the buccal and esophageal mucous membranes, attributed to Vitamin B deficiency, with buccal and esophageal cancer.

Rhoads¹³ has stressed the fact that many of the precancerous lesions are atrophic in nature. This is in accord with the observations that in experimental liver cancer produced by the carcinogenic chemical, butter yellow, atrophy of the liver cells precedes the development of cancer. Kensler and his associates¹⁴ have shown further that in experimental animals this process can be prevented by supplying extra quantities of riboflavin and casein in the diet.

From the standpoint of cancer control, the existence of precancerous

lesions presents the possibility of instituting case finding procedures to discover individuals having such lesions, to be followed by treatment where possible, and by continued observation so that if cancer develops, it may be treated early in its course.

CONSTITUTIONAL FACTORS IN HUMAN CANCER

Although certain of the precancerous lesions (leukoplakia, farmer's skin) are attributable to environmental agents, others such as familial intestinal polyposis and multiple neurofibromatosis are apparently the result of hereditary or at least familial influences. Further, even in the effects of identified exogenous carcinogenic agents, the degree of inherent susceptibility or resistance probably plays a rôle, as is indicated by the many workers who, although exposed for long periods to carcinogenic chemicals, do not develop cancer. As in most other diseases, both the constitutional factor and the environmental must be considered in the etiology of malignant tumors.

The information available concerning presumably constitutional factors affecting cancer incidence in man comprises data on (1) hereditary forms of cancer or of benign tumors; (2) the occurrence of cancer families; (3) the familial incidence of cancer; and (4) the incidence of secondary primary cancers in patients following successful treatment of first cancer.

In a few rare tumors a hereditary mechanism is generally accepted, although the effect of unknown environmental factors cannot be excluded entirely. Retinoblastoma of the eye occurs with sufficient frequency in siblings and in descendants of cured patients to justify advice against marriage or having more children. Examples of hereditary benign tumors are familial intestinal polyposis which occurs in one-third the children of affected fami-

lies and which becomes malignant in at least 25 per cent of cases; multiple neurofibromatosis which occurs in half the children if one parent is affected, and of which 13 per cent are reported to develop sarcoma; and certain benign bone tumors.

In addition, there have been described "cancer families," in which cancer, often of the same organ, such as the breast, uterus, or stomach, occurred in several brothers or sisters. What proportion of cancer patients come from such families is not known.

With regard to the common forms of cancer, studies have been made to determine whether the parents and siblings of cancer patients have any greater cancer mortality than the general population. The majority of such studies do show increased mortality in both parents and siblings, ranging from 20 to 60 per cent higher than expected. When cancer occurs in the same family, there is also a definite tendency for it to appear in the same organ.¹⁵⁻²⁰ It should be noted that such findings do not necessarily indicate a *general* familial concentration of cancer, but could be accounted for by assuming that a relatively small percentage of cancer patients come from cancer families. For example, in Crabtree's data,¹⁵ among 1,029 families there occurred an excess of 93 cancer deaths (37 per cent) over that expected in parents and siblings together. An increase above normal of one case in 9 per cent of the families would thus account for all of the observed excess of cancer deaths, with a normal incidence in the remaining 91 per cent of families. It is probably superfluous to point out that an increased familial incidence of cancer does not necessarily indicate that hereditary or genetic factors are responsible, since similar environmental factors may also run in families.

The evidence regarding familial cancer, although far from conclusive, is

sufficiently impressive so that in some clinics a family history of cancer, particularly of the breast and uterus, is regarded as indicating need for increased watchfulness for the possible development of a similar tumor in other members of the family. Certainly no objection will be raised to such an interpretation, which can lead only to increased chance of early diagnosis with correspondingly increased probability of successful treatment.

Obviously, the time has not yet come to look upon the occurrence of cancer in one member of a family as the signal for examination and continued follow-up of the patient's brothers and sisters. In identified cancer families this procedure is justified. Without further information, its employment in families where only one case has occurred would be experimental. The principle is being applied by some physicians and clinics, but it has not reached the stage of public health practice.

Related to the problem of the nature of inherent susceptibility to cancer is the question whether the development of cancer in one organ denotes an increased susceptibility to cancer in other parts of the body. This question has been approached by studying the subsequent incidence of other primary cancer in persons successfully treated for one malignant tumor. The subject has been investigated extensively by Peller,²¹ and more recently by Lombard and Warren.²² Their findings are similar and indicate that the incidence of second cancer is not significantly different from that of the general population. It should be emphasized that the opposite conclusion of Peller rests not on different findings but on the theoretical assumption that in cancer patients the subsequent expected incidence *should* be 5 times that of the general population. This is based on the further assumption that only 20 per cent of

the population are susceptible to cancer and, consequently, that among cancer patients, who are susceptible, of course, the annual age-specific mortality rates should be 5 times that of the general population. There is no known method of determining susceptibility to cancer and no reason to assume that only those who develop cancer are susceptible. The available experimental evidence indicates that environmental factors can alter incidence markedly.

From the practical standpoint the significant fact is that the incidence of second cancer in cancer patients is not greatly different from that of the general population. This suggests that increased susceptibility to cancer, whatever its nature, is not general but more probably is organ specific, as is the case in certain high tumor strains of mice and rats.

The rôle of hereditary factors in the causation of human cancer and the extent to which such factors are modifiable by environmental agents, remains obscure. There seems little doubt that such factors do exist for some tumors and in some families, but the available evidence indicates that they are of only minor importance in the majority of cases.

DIFFERENTIAL MORTALITY FROM CANCER

The known facts regarding the etiology of cancer, fragmentary as they are, can be correlated with only a few of the differential characteristics of cancer mortality. These characteristics, however, have intrinsic interest from the standpoint of a control program.

Although great stress has been laid on the errors of diagnosis inherent in mortality statistics of cancer, many of the differences in cancer mortality observed in different population groups are not readily explainable by diagnostic error. The extent to which

diagnostic errors are responsible for differences in mortality in different population groups must be considered separately for each group and each site of cancer where such differences are found.

TREND OF CANCER MORTALITY

The continued upward trend of cancer mortality has made cancer one of the major health problems of our time. One-third of the increase in mortality is due to increased "aging" of the population. The remaining increase is sometimes written off as reflecting increased recognition of cancer rather than increased incidence.

In upstate New York, comparison of age-standardized mortality from 1931 to 1941 shows an increase during this period of 10 per cent in male mortality; and a decrease of 6 per cent in female mortality. Mortality from cancer of the buccal cavity, skin, and lip, has decreased slightly in both sexes. Death rates from cancer of the stomach and the liver have decreased significantly in both sexes. Cancer of the breast increased only slightly; mortality from uterine cancer decreased by approximately 16 per cent. The increase in mortality from certain types of cancer in males is sufficient to raise the total mortality above that in the earlier period. The most marked increase occurred in cancer of the lungs and other respiratory organs, mortality from which increased threefold in males but only slightly in females. In females the decline in certain sites, notably the stomach, the liver, and the uterus, more than offsets the increased rate for other types of cancer. Since there is no reason to believe that diagnostic accuracy lessened during the past decade, it is probable that this decrease foreshadows a continued downward trend in cancer mortality among women.

From data regarding hospitalization of cancer cases and proportion of diag-

noses verified by pathological examination, there is no reason to believe that, for the same site of cancer, diagnostic accuracy is different in the two sexes. For this reason, as Gover has pointed out, the more rapid increase in mortality for certain internal types of cancer in males than in females is probably real and not due entirely to improved diagnosis.

CANCER MORTALITY BY COLOR AND GEOGRAPHIC REGIONS IN THE UNITED STATES

The possible association of cancer of the buccal cavity and of the liver with certain dietary deficiencies and the association of tongue cancer and probably cervix cancer with preëxisting syphilis suggest that mortality statistics in this country might reflect corresponding differences for cancer of these sites between geographic sections and between white and colored. For example, we might expect a relatively high mortality from buccal and liver cancer in those southern states with widespread gross dietary deficiency as indicated by high mortality from pellagra; also, colored males would be expected to have a higher mortality from tongue cancer; and colored females from cancer of the cervix.

Gover's data²⁴ for the years 1930 to 1932 show that age-standardized mortality from total cancer in both sexes in this country is highest in the Northeast and on the Pacific coast, lowest in the South and Southwest. The only exceptions are cancer of the skin, which is highest in the South, and cancer of the mouth and pharynx, which is highest in southern females and second highest in southern males. All other forms of cancer, including cancer of the liver and biliary passages, show lower rates in the South. These relative differences in site distribution of cancer between North and South appear in hospital deaths as well as in all

recorded deaths. The differences, however, are not so marked in morbidity data. The expected difference in cancer mortality in the South is thus present for buccal cavity cancer but not for cancer of the liver.

Comparison between white and colored cancer mortality in the United States shows that for most forms of cancer, colored mortality is lower than among whites. The differences are less marked in the North than in the South, presumably due to the fact that Negroes in the North obtain better medical care. A peculiar feature of cancer mortality in Negroes is that it is lower only in the age groups above 54 years; in younger age groups it is as high or slightly higher than among whites. Mortality from tongue cancer is lower in colored females, and only slightly higher in colored males than in whites.

The forms of cancer showing markedly higher mortality in the colored race are cancer of the external genitalia in males, and of the uterus and other female genital organs in females. The excess mortality from cancer of the uterus among colored women is 75 per cent in the South and 91 per cent in the North, and is sufficient to bring total cancer mortality among colored females slightly above that among whites in both sections of the country. In the experience of the Metropolitan Life Insurance Company's industrial department²⁵ from 1917 to 1935, the age-standardized mortality from uterine cancer among colored females was 55 per cent higher than among whites. We do not as yet have mortality data for cancer of the cervix uteri separated from that of the uterine fundus, but it is known that approximately 85 per cent of uterine cancers arise in the cervix.

The expected differences in cancer mortality between white and colored races because of the apparent associ-

ation of tongue and cervix cancer with syphilis are not found for tongue cancer, but are for uterine cancer. Obviously, such a finding is merely corroboratory and does not establish the fact of an association between syphilis and uterine cancer.

Regardless of its cause, the markedly high mortality from uterine cancer among colored females deserves greater attention than it has received, both from the standpoint of investigation and from that of administration of cancer control programs.

Cancer of the uterus and of the breast and ovary occur also with different frequency among women of different marital status. Uterine cancer mortality is highest among married women, while breast and ovarian cancer mortality is higher among single women. The mortality from breast cancer among childless married women is as high as in single women. The higher mortality from breast cancer among single women and childless married women is usually attributed to the absence of normal lactation, while the higher mortality from uterine cancer in married women has been interpreted as evidence that injuries resulting from childbirth are causes of uterine cancer. These interpretations have not been fully established. Recent data from Australia, described by Dorn,²⁶ indicate that uterine cancer mortality is highest among married women who have never borne children.

A more complete review of the differential mortality of cancer is not within the scope of this paper. It may be said, however, that most of the major forms of cancer exhibit sufficiently different epidemiological characteristics to indicate that each must be approached as a separate problem in cancer control.

SUMMARY AND DISCUSSION

In summary, there is evidence that the occurrence of human cancer is in

some cases attributable to the influence of specific chemical and physical agents; in others to an association with precancerous lesions and with other diseases; and, in a relatively small number of cases, familial factors, which may be hereditary, are operative. In a large proportion of cases, none of these etiologic factors can be identified. Considerable differences appear in mortality from various forms of cancer in persons of different race, economic status, and marital status. Most of these differences are not readily explainable by any single hypothesis regarding the causation of cancer.

Many of the etiologic and differential factors discussed point to possible public health applications in the form of special attention in education, in case finding and in follow-up directed to the groups which have an apparently high mortality and incidence of certain forms of cancer. Examples of such groups are: industrial and unskilled workers (cancer of the skin, lip, mouth, larynx, and stomach); unmarried women (cancer of the breast); syphilis patients (cancer of the vulva, cervix, tongue); Negro women (cancer of the uterus). The experience of the Strang Cancer Prevention Clinic in New York City, in case finding among apparently healthy women, indicates that the proportion of early cancer cases found is comparable to that of early cases of tuberculosis discovered by mass x-ray examinations.²⁷ Active case finding applied to groups with higher than normal incidence of cancer may be correspondingly more effective.

It seems reasonable to forecast that, in the future, cancer control programs will be guided to a greater extent than in the past by existing knowledge and by further investigation of the epidemiological characteristics of the disease. These point to a logical development of control activities directed toward population groups which apparently

stand in greatest need of such measures and among which they should prove most fruitful.

U. S. Cadet Nurse Corps Induction Pledge

At this moment of my induction into the United States Cadet Nurse Corps of the United States Public Health Service:

I am solemnly aware of the obligations I assume toward my country and toward my chosen profession.

I will follow faithfully the teachings of my instructors and the guidance of the physicians with whom I work;

I will hold in trust the finest traditions of nursing and the spirit of the corps;

I will keep my body strong, my mind alert, and my heart steadfast;

I will be kind, tolerant and understanding;

Above all, I will dedicate myself now and forever to the triumph of life over death.

As a Cadet Nurse, I pledge to my country my service in essential nursing for the duration of the war.

Serological Identification of Dysentery Bacilli*

KENNETH M. WHEELER, PH.D., F.A.P.H.A.

Research Microbiologist, Bureau of Laboratories, Connecticut State Department
of Health, Hartford, Conn.

THE diagnosis and control of bacillary dysentery is becoming an increasingly important public-health problem, especially during the war period.¹⁵ The laboratory is concerned with the problem of diagnosis, and must provide a rapid, accurate, and detailed examination with a report to the control official as quickly as is compatible with accuracy. Because of the nature of the infection, laboratory diagnosis has depended almost entirely on the isolation and identification of the causative organism from fecal specimens. Cultures are seldom isolated from blood and urine; agglutination reactions with patient's serum have been of little use; and bacteriophage tests have value only under special circumstances.¹⁶

Organisms of the *Shigella* genus constitute a heterogeneous collection both as to physiological properties and antigenic structure. Although several species have recognized pathogenic action, only two types, *Shigella paradysenteriae* (Flexner) and *S. sonnei* are commonly encountered in bacillary dysentery in the United States.¹⁵ *S. dysenteriae* (Shiga) and *S. ambigua* (Schmitz) are relatively rare, while *S. alkaescens* and *S. dispar* are generally considered of

doubtful pathogenicity. Considerable evidence has accumulated, however, to show that under certain conditions *S. alkaescens* has distinct pathogenic action,^{10, 13} and for the purposes of this discussion it will be considered with the pathogenic types. The New-castle organism, although it differs somewhat in biochemical properties, will be grouped with the Flexner types.

Identification of the dysentery organisms depends on morphological, cultural, physiological, and serological characteristics. Biochemical reactions are valuable for a tentative identification and especially for separation of the *dysenteriae-ambigua* section from the mannitol fermenting types. Other biochemical properties (fermentation of lactose, sucrose, maltose, rhamnose, arabinose, dulcitol, xylose, sorbitol, and production of indole) are useful for differentiating *S. paradysenteriae*, *S. sonnei*, and *S. alkaescens* species. Occasionally epidemic strains can be identified by a physiological peculiarity. For type differentiation within the paradysentery group, however, fermentation reactions are of little value. In other instances, such as lactose fermentation by *S. sonnei*, many days are required to complete the reactions. Serological methods offer the advantages of accuracy and speed and permit a more complete description than can be obtained from biochemical study. The slide aggluti-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-second Annual Meeting, New York, N. Y., October 13, 1943.

nation test with specific sera is a simple, rapid, and inexpensive method of serological identification. Within the Flexner group, especially, the advantages of this method are apparent when applied to strain typing.

The basis for the serological differentiation of paradysentery types is the work of Boyd^{5,6} who described six different sero-types each possessing a specific antigen but related by one or more common group antigens. These included the V, W, and Z strains of Andrewes and Inman,¹ the Newcastle or type 88 strain as well as two other types, 103 and P119. Six additional less frequently encountered paradysentery types (170, P288, P274, D1, D19, P143) also were described which possessed no group antigen or only minor antigens of the Flexner organisms. Our examination of the *S. paradysenteriae* strains has confirmed the presence of specific antigens and has identified nine components of the group antigen distributed among the various Flexner types.¹⁷ An additional W serotype was defined by marked differences from the standard strain in group antigen, and epidemiological studies of this variety have shown it to be a valid type. The

X and Y strains had no significant type-specific antigens and probably should not be considered as separate types but as variants of other types.

The nomenclature for the Flexner group proposed by Boyd⁶ provides a simplification and clarification of terminology and a practical basis for identification. This terminology will be used in the following discussion. The V, W, Z, 103, P119, and 88 (Newcastle) types have been designated by Roman numbers I through VI. It seemed advisable¹⁷ to divide the II or W group into two sections II_a and II_b, on the basis of differences in group antigen. Departures have been made from Boyd's scheme in assigning arabic numbers to the components of the group antigen. Four of these components have been used in the strain typing methods although all are not essential for identification of the serological types. These fractions are designated by numbers as follows: 4 present in I, II_a, Y, and VI types; 5 in I and V types; 6 in I, III, and some IV types; 7 in II_b, III, V, and the old type X strains.

The other Boyd cultures gave some cross-reactions with the Flexner types,
